Bond Activation and Catalysis by Nontrigonal Tricoordinate and Tetracoordinate Phosphorus Compounds

by

Yi-Chun Lin

Submitted to the Department of Chemistry in Partial Fulfillment of the Requirements for the Degree of Doctor of Philosophy in Chemistry

ABSTRACT

Molecular distortion has a profound impact on the electronic structure and reactivity of molecules. This dissertation describes studies on E-H bond activation and catalytic reactivity of σ^3 - and σ^4 -phosphorus compounds with distorted nontrigonal structures. Specifically, a rare example of N-H oxidative addition to a planar, C_{2v} -symmetric P(III) center is described in Chapter 2. The kinetics and computational studies implicate a noncanonical, phosphorus-based electrophilic pathway for this transformation. As detailed in Chapter 3, a C_s -symmetric phosphorous triamide and its P-N cooperative reactivity are presented. B-H activation and catalytic imine hydroboration are achieved via the combination of the electrophilic phosphorus center and the basic anilide ligand moiety of this C_s -symmetric phosphorus compound. Finally, Chapter 4 extends the study of distorted phosphorus compounds to σ^4 -phosphorus molecules. Iminophosphoranes bearing constrained ligand platforms are synthesized and their distortion-induced B-H, B-O and Si-H bond activation reactivity are presented. This research provides insight into the influence of molecular symmetry on the reactivity of σ^3 - and σ^4 -phosphorus compounds and represents an initial step toward the discovery of new chemistry in other distorted phosphorus molecules.

Thesis Supervisor: Alexander T. Radosevich
Title: Associate Professor of Chemistry

Acknowledgements

I never expected that my life as a graduate student would be completed here when I first came to the United States, but now I have arrived at the end of this fascinating journey after so many challenges and difficulties. I am so grateful to all the people who helped me along the way and I could never do this without their help.

I can never thank Professor Alex Radosevich enough. Alex, thank you for reintroducing chemistry to me with your extraordinarily broad knowledge and guiding my research with the creative ideas. Thank you for always been supportive and patient, and willing to tolerating and encouraging me when I was at my low points in life. I have learned a tremendous amount of knowledge in both science and life through the interactions with you and I would bring it forward to my next step. I would also like to thank Professor Cummins and Professor Dinca for their valuable advice and suggestions on my research and thesis.

I was blessed to be in the Radosevich group and had the pleasure to work with all members of the group. Kyle Reichl, Nicole Dunn, Wei Zhao, Eric Miller, Ajay Sathe, Shi Liu, Ryan Byrne and Rixin Wang, we learned a lot together and did so many unforgettable and stupid things together during those early days at Penn State. Samantha Damiano, Charlie Lai, Nick Fastuca and Allen Pistner, thank you for bringing so much laugh into the lab. Jared Mattos, Trevor Nykaza and Tyler Harrison, we did an incredible job moving the lab to here and I want to thank you for helping me much here in Boston. Avipsa Ghosh, Ayan Maity, Greg Cleveland, Connor Gilhula, Hye Won Moon and Akira Tanushi, knowing you is one of the best things from the lab relocation, and I will miss all those smart and not-so-smart ideas we generated together. Wishing you all the best in your future endeavors.

Finally, I would like to give my thanks to my family. Mom and dad, thank you for all the supports and encouragements. My little brother, thanks for taking care of mom and dad when I was away. Pin-Hua, thank you for always being there for me no matter what. This thesis never would have happened without your support.

Table of Contents

List of Figures.....	8
List of Tables.....	16

Chapter One

Geometrical Distortion of σ^3-Phosphorus and σ^4-Phosphorus Molecules as a Route to Non-canonical Reactivity	21
1.1 The Influence of Geometrical Distortion on Molecular Electronic Structure and Chemical Behavior	23
1.2 Geometry of Traditional σ^3 -Phosphorus and σ^4 -Phosphorus Molecules and Their Reactivity.....	30
1.3 Unusual Reactivity of Geometrically Constrained Phosphorus Molecules	32
1.4 Conclusion and Outlook.....	43
1.5 References	43

Chapter Two

N-H Oxidative Addition Reactivity of a T-Shaped Phosphorus Compound.....	47
2.1 Significance and Challenges of N-H Activation	48
2.2 Metal- and Main Group Element-Mediated N-H Oxidative Addition	49
2.3 Intermolecular N-H Oxidative Addition to the T-Shape O,N,O- σ^3 -Phosphorus Molecule	52
2.4 Structure of the N-H Oxidative Addition Product.....	59

2.5	Thermodynamic Analysis of the N-H Oxidative Addition Process	61
2.6	N-H Elimination and Amine Exchange of the Phosphorane Adducts	63
2.7	Mechanistic Analysis of the N-H Oxidative Addition Process	65
2.7.1	Deuterium Labeling Study of N-H Oxidative Addition	68
2.7.2	UV-Vis Spectra of Compound 2.3 and 2.5a for Kinetic Study	69
2.7.3	Determination of Reaction Order in Phosphine 2.3 in Pseudo-First Order Condition....	71
2.7.4	Determination of Reaction Order in Amine in Pseudo-First Order Condition	73
2.7.5	Eyring Plot for Activation Parameters	74
2.8	DFT Investigation of the N-H Oxidative Addition	75
2.9	Conclusion and Outlook.....	79
2.10	Experimental	81
2.11	References	94

Chapter Three

Phosphorus-ligand Cooperative B-H Activation and Catalytic Hydroboration by a C_5 -Symmetric N,N,N- σ^3 -Phosphorus Molecule

98

3.1	Geometry, Electronic Structure and Reactivity of the C_5 - symmetric N,N,N-Phosphorus Molecule	100
3.2	Stoichiometric Phosphorus-Ligand Cooperative B-H Activation.....	105
3.3	Characterization of the P-Hydrido-Diazaphospholene Intermediate	107
3.4	Hydridic Reactivity of the P-hydrido-diazaphospholene 3.6 toward Alkyl Halides and Imines	109

Chapter One

Geometrical Distortion of σ^3 -Phosphorus and σ^4 -Phosphorus Molecules as a Route to Non-canonical Reactivity

This dissertation presents investigations on geometrically deformed phosphorus molecules and their unique reactivity in stoichiometric and catalytic transformations. Organophosphorus molecules, especially tricoordinate phosphorus compounds, have long been known for their roles as synthetic reagents in chemical synthesis and ligands in organometallic chemistry. The well-known reactivity of tricoordinate organophosphorus molecules results predominately from the Lewis basic nature of the phosphorus lone pair, giving rise to nucleophilic applications. However, geometric distortion of organophosphorus molecules away from local threefold pseudosymmetry reconstructs their orbital diagram and unleashes their potential for non-canonical phosphorus-mediated transformations. This dissertation discusses the structural distortions of several tricoordinate and tetracoordinate organophosphorus molecules and their resulting non-traditional chemical behaviors, in both biphilic reactivity and E-H bond activations. Chapter 1 provides an overview of how geometrical modifications impact the bonding and reactivity of molecules, with several examples of these influences in organophosphorus chemistry.

1.1 The Influence of Geometrical Distortion on Molecular Electronic Structure and Chemical Behavior

Discovery of unprecedented reactivity is a major thrust that drives the understanding of chemistry forward. The reactivity of a molecule in a particular transformation can be controlled by a range of external variables, but the electronic structure of a molecule is the most crucial determinant that shapes how it interacts with other molecules.¹ Whereas electronic energy has been frequently invoked to rationalize ground state (equilibrium) molecular geometry,² the deliberate perturbation of molecular geometry distortion³ as a means to access desired electronic structure (and consequently reactivity) is comparably less investigated and practiced.

Molecular distortion and the resulting change in molecular symmetry have profound consequences upon the energy level, shape and localization of molecular orbitals, and this phenomenon can be exemplified by even the simplest molecules. The imaginary molecule H_4 serves as an illustrative example,⁴ where three possible molecular geometries can be considered (**Figure 1.1**): linear ($D_{\infty h}$), square (D_{4h}) and tetrahedral (T_d). The square planar H_4 molecule can be considered a geometric distortion from the linear H_4 molecule. Similarly, the tetrahedral H_4 molecule can be imagined as the result of the flexing of the square planar H_4 structure. The significant change in the electronic structure of H_4 upon distortion from linear to tetrahedral geometry is demonstrated by qualitative molecular orbital analysis (**Figure 1.1**). During the distortion from linear to square planar geometry, the $1\sigma_u$ and two σ_g MOs of the original $D_{\infty h}$ molecule approach each other in energy and eventually become the degenerate e_u MOs in the D_{4h} molecule.

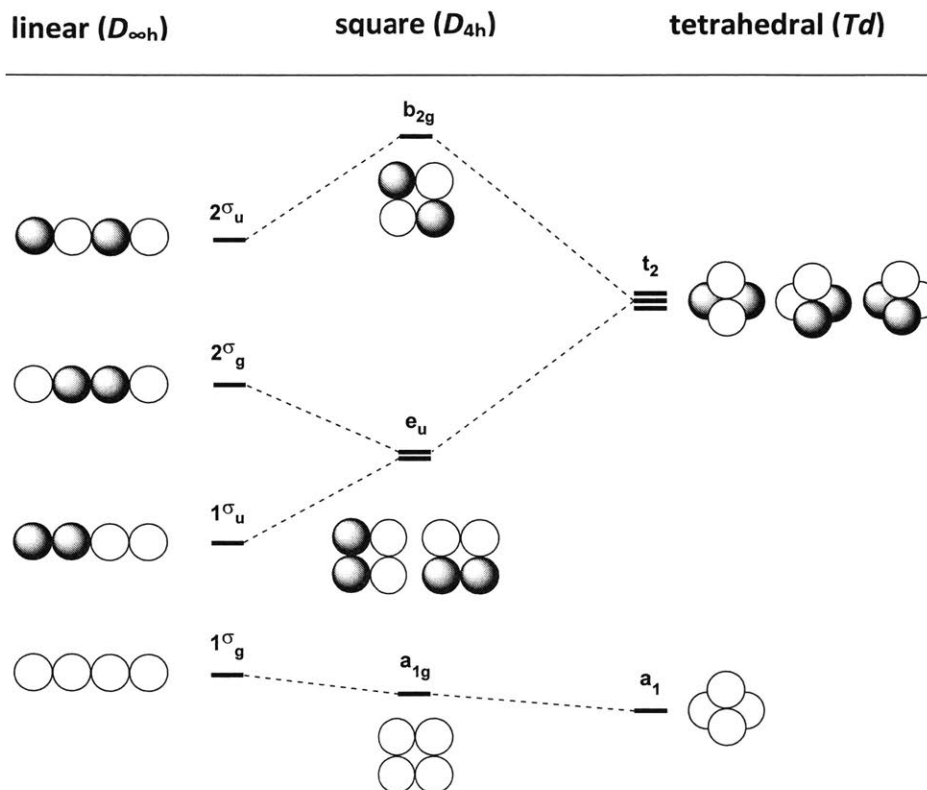

Figure 1.1. Qualitative MO correlation diagram for linear and square planar H₄ molecule.

While the a_{1g} MO of D_{4h} molecule is only slightly stabilized due to the in-phase interaction of terminal hydrogen s orbitals, the transition from $D_{\infty h}$ $1\sigma_u$ to D_{4h} e_u rises significantly in energy level because of the out-of-phase interaction of terminal hydrogen s orbitals. Based on this qualitative MO analysis, a neutral H₄ molecule which contains four valence electrons would have a rising HOMO and therefore suffer a loss in stability during the linear to square planar distortion. With the same concept, HOMO (e_u) orbitals of neutral square planar H₄ transform into the high energy t_2 orbitals of tetrahedral H₄ and result in an even higher HOMO amid the D_{4h} - T_d distortion. Taking into account the strong Jahn-Teller effect in the t_2 orbitals, distortion of a neutral H₄ molecule to

tetrahedral geometry would transform the molecule to a more reactive species with better electron affinity and lower ionization energy.

The impact of geometry distortion demonstrated by the imaginary H_4 molecule can also be witnessed in real and more elaborate molecules. For instance, the molecular orbitals of a typical AH_3 molecule are constructed from the s orbitals of the central A atom and three peripheral hydrogens and p orbitals of the A atom. Due to the directional nature of p orbitals, molecular geometry exerts even more influence on the resulting AH_3 molecular orbitals (**Figure 1.2**).⁵ With eight valence electrons, PH_3 is a pyramidal (C_{3v}) compound and has $2a_1$ and $3a_1$ orbitals as its HOMO and LUMO. Upon distortion from its original pyramidal to planar (D_{3h}) geometry, PH_3 gradually loses bonding interaction in its HOMO $2a_1$ orbital and becomes less stable as the hydrogen atomic s orbitals move into the central nodal surface of the orbital. On the other hand, the original C_{3v} LUMO $3a_1$ orbital would be stabilized and become more accessible due to the decreasing AO antibonding interactions. Necessarily, PH_3 undergoes a HOMO-LUMO energy gap contraction after the transition from pyramidal to planar geometry and affords better nucleophilicity and electrophilicity at the same time. Further PH_3 deformation from the planar geometry would likely make the compound even more reactive. Considering the desymmetrization from planar to T-shaped (C_{2v}) geometry, the original $1a_2''$ HOMO transforms into the $1b_1$ orbital with no stabilization change because no interaction exists between phosphorus and hydrogens in both orbitals. In contrast, the original $2a_1'$ LUMO is gradually stabilized and eventually turns into the $3a_1$ orbital due to the bonding interaction between two basal hydrogens and axial hydrogen. Therefore, the resulting T-shaped PH_3 molecule has an even more energetically accessible LUMO than D_{3h} PH_3

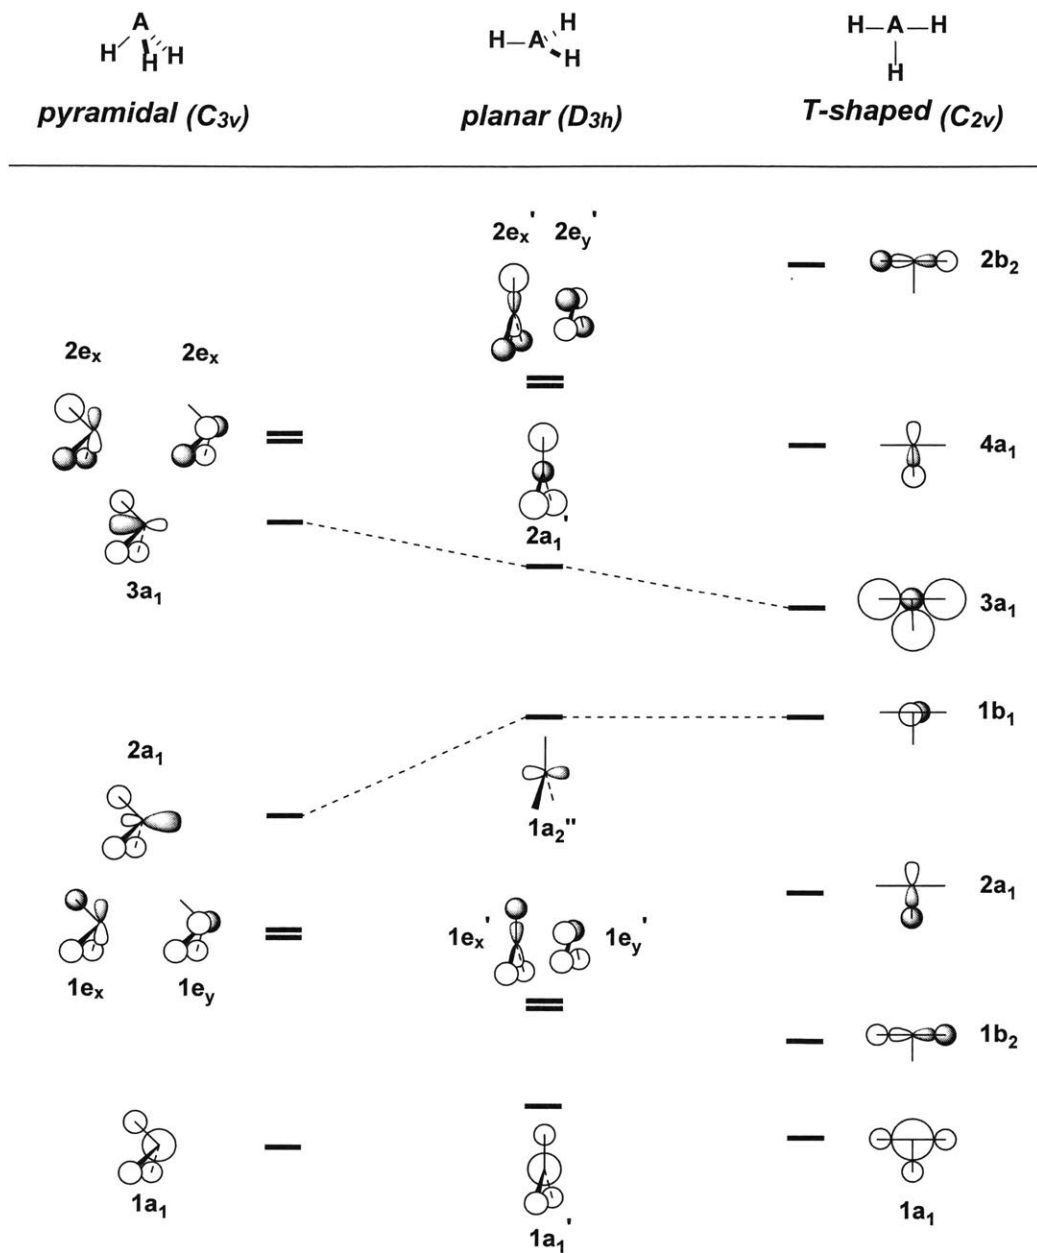

Figure 1.2. Qualitative MO correlation diagram for pyramidal, planar and T-shaped AH₃ molecules.⁵

after distortion and may endow the phosphine compound with noncanonical electrophilic reactivity. The geometry induced rearrangement of AH₃ molecular orbitals also explains the preference of planar geometry for species which contain less than seven valence

electrons in the ground state, such as BH_3 or CH_3^+ . In contrast to PH_3 , HOMO-LUMO energy gap contraction happens when these molecules distort their geometry from their planar structure to pyramidal geometry.

Molecules with a central atom permitting various coordination numbers can be more versatile in their molecular geometries and thus offer even more possibilities to access unusual electronic structures and reactivity. Depending on the valence electron count of the molecule, tetracoordinate AB_4 molecules can adopt a variety of geometries including tetrahedral (T_d), planar (D_{4h}) and C_{2v} geometries. Similar correlations between molecular geometry and electronic structure of tetracoordinate AB_4 molecules can be demonstrated again with the qualitative MO diagram (**Figure 1.3**).⁶ Consider again a molecule with an eight valence electron count, PF_4^+ for example, LUMO stabilization and HOMO destabilization occur along the distortion from tetrahedral to planar to C_{2v} geometry because of the movement of ligands into the central nodal surface. Along with the geometrical versatility, the instability imposed by this mode of frontier orbital energy level contraction makes the AB_4 molecules valuable in the discovery of new reactivity.

In concert with the orbital considerations above, one might also consider the enthalpic impact of molecular distortions. Necessarily, the deviation from equilibrium geometry for a molecule results in an increase in overall energy that can be described as strain. Targeted release of this strain energy can serve as a driving force to enable otherwise nontypical reactions.¹ Such an approach is commonly utilized in a variety of synthetic procedures, as can be exemplified in ring-opening reactions of cyclopropanes,⁷ epoxides,⁸ aziridines,⁹ including ring-opening metathesis polymerization.¹⁰

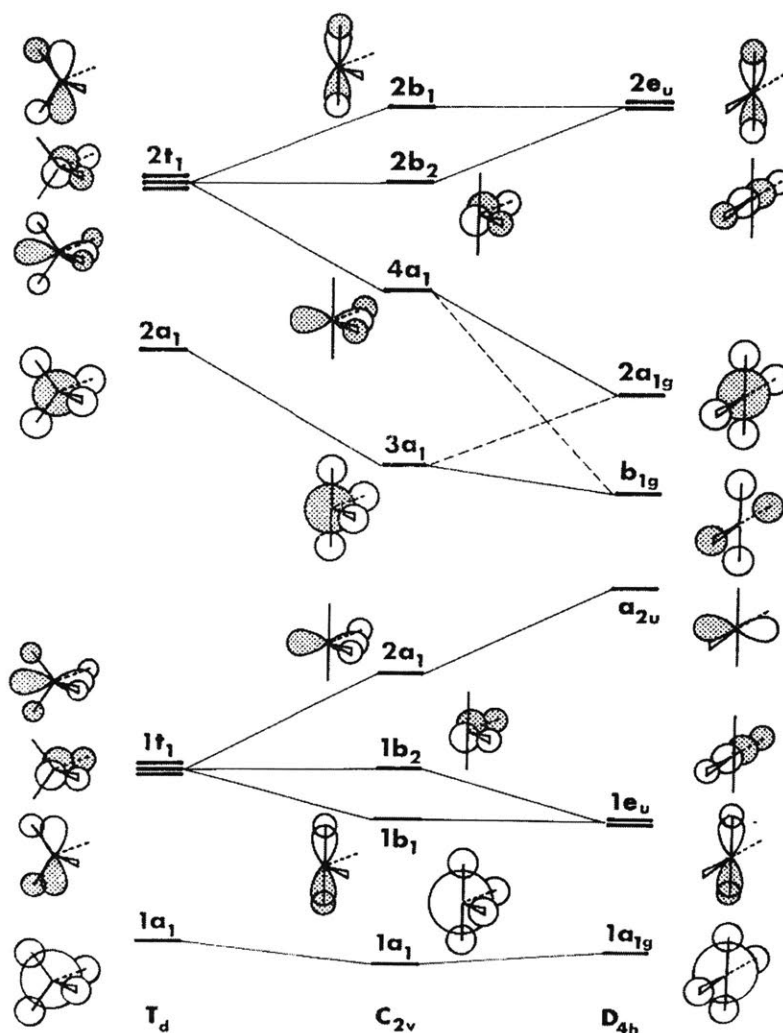

Figure 1.3. Qualitative MO correlation diagram for tetrahedral (T_d), C_{2v} and planar (D_{4h}) AB_4 molecules. Reproduced with permission from *J. Am. Chem. Soc.* **1978**, *100*, 2340.

The foregoing ‘ground state destabilization’ notion for altering reaction thermodynamics has a kinetic corollary. By enforcing a structural and energetic similarity between reactant and transition state, the required energy input for structural reorganization from starting species to transition state would be minimized, thereby speeding reactivity. It has been postulated that certain enzymatic catalysts operate in this

fashion, in which the supporting protein structures distort active metal centers into reactive “entatic states” and facilitate the enzymatic transformations.¹¹ Several theoretical and experimental investigations of similar strategies can also be found in organic and main-group chemistry, including the reactivity studies of the distorted alkynes¹² and phosphorus compounds.¹³

As presented above, geometric deformation of a substrate, reagent or catalyst can result in drastic changes in reactivity through frontier orbital rearrangement, structural strain imposition or reorganization energy minimization. It is a motivating hypothesis within the Radosevich laboratory that these considerations are underutilized as design principles in main group reactivity and catalysis. Organophosphorus compounds, for instance, are widely employed in synthesis but are limited in the ways that they are used. With the powerful influence of geometric distortion on AB_3 and AB_4 electronic structure in mind, we aimed to discover novel reactivity of distorted σ^3 -phosphorus and σ^4 -phosphorus molecules by designing new deformed structures. In doing so, we have also revisited known molecules to unleash their unrealized potential (**Figure 2.4**).

Figure 1.4. Molecular distortion of σ^3 -phosphorus and σ^4 -phosphorus molecules.

1.2 Geometry of Traditional σ^3 -Phosphorus and σ^4 -Phosphorus Molecules and Their Reactivity

The purpose of this section is to address the geometry and reactivity of traditional σ^3 -phosphorus and σ^4 -phosphorus molecules and use the information to discuss the potential reactivity changes of distorted phosphorus molecules. Traditional phosphines are tricoordinate molecules with pyramidal structure and a phosphorus-based lone pair. The lone pair is stereochemically active, pointing away from the three ligands of the pyramidal phosphines. The unhindered environment, along with the relatively large size and low electronegativity of the phosphorus atom, makes the lone pair easily susceptible to nucleophilic interaction with electrophiles. By consequence, the reactivity of pyramidal σ^3 -phosphorus molecules results overwhelmingly from the nucleophilicity of this lone pair. In addition, phosphines are easily oxidized to the P(V) oxidation state and produce robust P=O bonds. The strong P=O bond makes phosphines capable reagents for mediating deoxygenative transformations.¹⁴

Because of their nucleophilic and oxophilic nature, phosphines are useful reagents in synthetic chemistry for constructing and modifying organic molecules. For instance, phosphines are used to catalyze the coupling of an activated alkene and an aldehyde in the Morita-Baylis-Hillman, proceeding via initial 1,4-nucleophilic addition of the phosphine to the conjugated alkene.¹⁵ In stoichiometric phosphine-mediated transformations, such as Wittig,¹⁶ Mitsunobu¹⁷ and Appel¹⁸ reactions, the nucleophilic interaction of the phosphine reagent and an electrophilic substrate generate a

phosphonium intermediate, which then further reacts through P=O elimination to afford the observed products.

In addition to their direct participation in chemical transformations, phosphines are also used as ancillary ligands in organometallic chemistry.¹⁹ With the combination of their electron-donating nature, versatile substitution patterns and available π -accepting orbitals, phosphines make ideal ligands for transition metals and play a crucial role in catalysis. Furthermore, phosphines exhibit much a higher inversion barrier (30–40 kcal/mol)²⁰ than their nitrogen congeners (5-10 kcal/mol)²¹ due to the lower electronegativity of the phosphorus atom, and thus can be prepared as P-stereogenic ligands for stereoselective metal-based catalysis such as asymmetric hydrogenation.²²

Figure 1.5. Tetracoordinate phosphorus compounds with traditional pseudo-tetrahedral geometry.

Tetracoordinate phosphorus compounds (**Figure 1.5**) are traditionally most stable in pseudo-tetrahedral geometry as predicted by VSEPR and AB_4 qualitative MO analysis. Without the nucleophilic lone pair on the phosphorus atom, σ^4 -phosphorus compounds such as iminophosphoranes are generally less reactive and less frequently utilized in synthetic chemistry than σ^3 -phosphorus compounds. Iminophosphoranes are σ^4 -phosphorus molecules with double bonded nitrogen on the phosphorus atom. Without the lone pair, iminophosphoranes also have relatively unreactive phosphorus centers but can

still be useful reagents or precursors in the synthesis of amines,²³ amides²⁴ and heterocyclic compounds.²⁵ In particular, iminophosphoranes can be used in the aza-Wittig reaction to convert carbonyl compounds to imine molecules by utilizing the oxophilic nature of phosphorus atom.²⁶ The combination of the strong Lewis basic P=N nitrogen and low Lewis acidic phosphorus also makes iminophosphorane an ideal structural moiety for organic superbases and useful in Lewis-base-catalyzed transformations.²⁷ On the other hand, chiral phosphoric acids with chiral BINOL substituents are another example of σ^4 -phosphorus molecules that have recently drawn attention for their applications in acid-catalyzed stereoselective transformations.²⁸

1.3 Unusual Reactivity of Geometrically Constrained Phosphorus Molecules

As discussed above, the reactivity of σ^3 -phosphorus compounds is mostly described by the nucleophilicity of their P-based lone pairs, and the reactivity of σ^4 -phosphorus molecules usually arises from their P-substituents instead of the phosphorus center. However, several examples of distortion-induced nonconventional σ^3 - and σ^4 -phosphorus-based reactivity can be found in the literature and may provide information for designing new phosphorus compounds with novel reactivity.

Tris(dialkylamino)phosphine molecules exhibit unusual nontrigonal geometries as compared to other pyramidal σ^3 -phosphorus compounds. The simple tris(dialkylamino)phosphine molecule $\text{P}(\text{NMe}_2)_3$ adopts a ground state C_s molecular symmetry due to the repulsions between N and P lone pairs and other unknown

intramolecular electronic interactions.²⁹ Further geometric deviation in the structures of other $P(NR_2)_3$ compounds give molecules of unusual reactivity. For instance, intramolecular N-H oxidative addition reactivity is observed by Richman and Atkins during their studies of cyclam derived phosphorus compounds (**Figure 1.6**).³⁰ Caged phosphorus compounds with small ring structures, such as compound **1.1a**, generated only σ^5 -hydridophosphorane product **1.2a**. By contrast, larger ring analogues from **1.1c** prefer the tricoordinate structure **1.3c**. An explanation for this observation is that the undetectable phosphine intermediate **1.3a** is unstable due to the geometry deformation enforced by the small bicyclic ligand. With the inherent proximity of the phosphorus atom and the pendant N-H group, the phosphine intermediate is quickly intercepted by the pendant N-H through a non-nucleophilic mechanism and gives the formal intramolecular N-H oxidative addition product. With the expansion of the phosphabicyclic ring and the relieved molecular distortion, larger bicyclic phosphine products such as **1.3 b** and **1.3c** lose their intramolecular phosphorus-based N-H activation reactivity and thus can be observed as the P(III) isomeric form.

Along these same lines of reasoning, bicyclic O,N,O-phosphine **1.5** (**Figure 1.7**) was studied. Here, Wolf³¹ and Denney³² observed a P-hydridophosphorane compound **1.6** resulted from the N-H oxidative addition of Me_2NH to the phosphorus atom when diethanolamine **1.4** was mixed with $P(NMe_2)_3$. Upon heating, the phosphorane **1.6** undergoes N-H reductive elimination and converts back to phosphorus compound **1.5**. By virtue of the apparent intermolecular N-H oxidative addition, O,N,O-phosphine **1.5** is presumably more reactive than the N,N,N-phosphine **1.1** in a similar distorted geometry.

Figure 1.6. Synthesis of the cage tetra-aza-phosphorus compounds and the observed P(III)-P(V) equilibrium.

Figure 1.7. Synthesis of bicyclic O,N,O-phosphine **1.5** and its intermolecular N-H oxidative addition reactivity.

Bicyclic O,N,O-phosphine **1.5** is also reactive in oxidative addition of alcohol O-H bonds (**Figure 1.8**) and the resulting phosphorane product can be observed with ^{31}P NMR spectroscopy.^{31a} Furthermore, a product equilibrium of the P-hydridophosphorane and a ring-opened species was observed when using phenol as the substrate alcohol in this transformation, indicating the mechanism involves an initial addition of nucleophilic -OH into the phosphorus center of **1.5** and a subsequent P(III)-P(V) tautomerization to afford the phosphorane product (**Figure 1.9**). In addition to O-H bonds, compound **1.5** also reacts toward a variety of nonpolar bonds including O-S and S-S and gives the formal oxidative addition products (**Figure 1.10**).³² With a similar strained chelating structure, benzannulated O,N,O-phosphabicyclic compound **1.11** also shows intermolecular oxidative addition reactivity toward carboxylic O-H bonds (**Figure 1.11**), although the resulting P-hydridophosphorane **1.12** and ring-opened P(III) product **1.13** are fleeting intermediates that ultimately decompose to final product **1.15**.³³

As a further an indication of the importance of ring size on reactivity at phosphorus, O,N,O-phosphabicyclic compound **1.17** – which has an expanded ring and

Figure 1.9. Reversible O-H oxidative addition of **1.5** toward PhOH and the product P(III)-P(V) equilibrium.

Figure 1.10. S-O and S-S oxidative addition of **1.5**.

less distorted structure – loses its N-H oxidative addition reactivity and gives no P-hydridophosphorane upon exposure to Me_2NH (**Figure 1.12**).³²

With the above mentioned unusual bond activation reactivity of the deformed N,N,N- and O,N,O-bicyclic phosphines in mind, one can expect that further distortion of the phosphabicyclic structure to a planar geometry would cause even greater propensity for nonnucleophilic reactivity. O,N,O-bicyclic phosphine **1.18** synthesized by Arduengo³⁴ has a remarkable planar structure and a similar O,N,O-[3,3,0]-bicyclic binding motif as phosphines **1.5**, but the ethylene linkages in **1.5** are replaced by unsaturated ethenyl fragments (**Figure 1.13**). X-ray crystallography of compound **1.18** shows a planar T-shaped geometry with a large O-P-O angle (168.8°) and acute N-P-O

Figure 1.11. O-H oxidative addition of **1.5** toward carboxylic acid and the proposed product decomposition.

angles (84.0° and 84.9°). Several Lewis structural descriptions of the compound **1.18** have been proposed to explain its geometry (**Figure 1.14**).³⁵ The major factor contributing to the preference of planar geometry is the presence of the vinylic moiety which makes the O,N,O-ligand more electron rich and capable of donating electron density to the phosphorus atom. The extra electron density from the oxygen and nitrogen atoms and the strain imposed by the unsaturated ligand give phosphine **1.18** a formal ten valence electron count on the tricoordinate phosphorus center and subsequent T-shape planar geometry with apical oxygens and equatorial nitrogen. From the perspective of molecular orbital theory, lone pairs on the ligand nitrogen and oxygens donate electron density to the out-of-plane phosphorus p orbital, stabilizing the planar structure. In such a bonding arrangement, the stabilized out-of-plane phosphorus p orbital, the linear O-P-O bond and the rectangular N-P-O angles leave little p-character for the phosphorus lone

pair orbital and thus make the lone pair high s-character and significantly less nucleophilic.

Figure 1.13. Synthesis of T-shaped O,N,O-phosphabicyclic compound **1.18**.

Figure 1.16. Visualized LUMO and HOMO of compound **1.18**.

Figure 1.17. Reactivity of compound **1.18** toward methanol.

In line with the predictions from qualitative MO analysis of distorted AB_3 molecules, calculations indicate that T-shaped compound **1.18** have a significantly stabilized LUMO as compared to $P(NM_2)(OMe)_2$. In effect, compound **1.18** has a much smaller HOMO-LUMO gap than a traditional C_{3v} phosphine (**Figure 1.15**). Furthermore, depictions of the LUMO of compound **1.18** (**Figure 1.16**) reveal that the orbital contains significant lobal density on the phosphorus atom. Similar to the distorted O,N,O-bicyclic phosphine **1.5**, when compound **1.18** is treated with methanol (**Figure 1.17**), a P-hydrido phosphorane intermediate **1.19** with a strong $^1J_{P-H}$ coupling can be detected by ^{31}P NMR spectroscopy. Following proton transfer and ligand tautomerization, final product **1.20** is generated. More recently, our group discovered that compound **1.18** can dehydrogenate ammonia borane to produce dihydridophosphorane **1.21** (**Figure 1.18**).³⁶ The dihydridophosphorane **1.21** can further be used to reduce azobenzene through a bimolecular mechanism with low activation barrier. By combination of the two stoichiometric transformations, compound **1.18** catalyzes transfer hydrogenation of azobenzene using ammonia borane as the terminal reductant (**Figure 1.18**).

Figure 1.18 Transfer hydrogenation of azobenzene catalyzed by compound **1.18**.

Besides the distorted phosphabicyclic systems, several examples of geometry-induced non-traditional phosphorus-mediated chemistry have also been demonstrated by our group. Deformed phosphorus molecules with 4-membered phosphetane structures are shown to be efficient reagents or catalysts in transformations including deoxygenative condensation,³⁷ regioselective allylic reduction³⁸ and Cadogan-type N-N bond formation (**Figure 3.19**).³⁹ From mechanistic and computational studies, the unprecedented reactivity is unleashed by the stabilized LUMO of the deformed phosphetane molecules which facilitates the electrophilic interactions between the phosphorus centers and the incoming nucleophiles such as hydrides or silanes. In addition, the transformations are favored due to the minimized reorganization energy required for the conversions from

starting reagents to transition states because of the forced entatic geometries of the phosphorus intermediates.

Figure 1.19. Catalytic reactivity of the phosphacyclic molecules with strained phosphetane structures.

1.4 Conclusion and Outlook

In view of the foregoing discussion of ring-constraint on the reactivity of tricoordinate phosphorus, it would appear that an as-yet-unrealized opportunity presents itself for the deliberate design of lower symmetry phosphorus compounds with nonnucleophilic reactivity. Through the research in this thesis, we hope to better understand the interplay between geometry and reactivity by studying nontrigonal σ^3 - and σ^4 -phosphorus compounds. The knowledge obtained in the research could help us to establish a general understanding of distortion-reactivity relationships, and thereby develop novel functionalization methods for synthetic chemistry.

Chapter Two. N-H Oxidative Addition Reactivity of a T-Shaped Phosphorus Compound

A significant portion of the work described in this chapter has been published in:

McCarthy, S. M.; Lin, Y.-C.; Devarajan, D.; Chang, J. W.; Yennawar, H. P.; Rioux, R. M.; Ess, D. H.; Radosevich, A. T. *J. Am. Chem. Soc.* **2014**, *136*, 4640.

Chapter Two

N-H Oxidative Addition Reactivity of a T-Shaped Phosphorus Compound

With the aim of investigating the impact of geometric distortion on reactivity of tricoordinate phosphorus molecules, we present here the study of N-H oxidative addition reactivity of a geometrically unique T-shaped phosphorus compound.¹ Arduengo's C_{2v} -symmetric O,N,O-phosphabicyclic P(III) molecule was found to undergo N-H oxidative addition with ammonia and other primary amines to generate the corresponding P(V) products. The resulting phosphorane products from this transformation provide the first example of stable intermolecular phosphorus-based N-H activation products for isolation, spectroscopic characterization and in-depth mechanistic study.

2.1 Significance and Challenges of N-H Activation

Oxidative addition is an important elementary reaction type, with a crucial role that can be witnessed in the remarkable success of many transition metal catalyzed methods. The oxidative addition of N-H bonds is of considerable interest in connection with potential schemes for transforming nitrogen-based commodity feedstocks into value-added medicinal or consumer products. However, examples of N-H oxidative addition are rare by comparison to the many analogous E-H bond activations that

currently figure in large number of prominent transition metal-based catalytic functionalizations.² In particular, catalytic amination of aromatics and olefins with ammonia has been listed among the most valuable goals in industrial chemistry.³

The challenges associated with N-H bond activation and functionalization can be rationalized by several aspects. First, the high bond dissociation energies (90-110 kcal/mol)⁴ and low acidity of N-H bonds ($pK_a = 35-40$)⁵ make activation thermodynamically disfavored via both homolytic and heterolytic pathways. Second, late transition metals that are frequently used in E-H activations easily coordinate with the Lewis-basic ammonia and amine, forming stable Werner-type adducts. Despite these challenges, several examples of N-H oxidative addition to both transition metals and main group species have been reported, providing potential directions in the development of N-H functionalization methods.

2.2 Metal- and Main Group Element-Mediated N-H Oxidative Addition

Although recent N-H activation examples associated with bimetallic⁶ and metal-ligand cooperative⁷ systems have been reported, well-characterized studies of N-H oxidative addition to a single-site metal centers remain rare. Milstein et al.⁸ first demonstrated in pioneering studies that some tetracoordinate iridium(I) compounds are reactive toward ammonia through oxidative addition and produce amido hydrido Ir(III)

complexes. A subsequent advancement was achieved by Hartwig with an aliphatic ligand-bearing iridium(I) P,C,P-pincer complex **2.1** (Figure 2.1).⁹ With the relatively electron-donating aliphatic P,C,P-ligand, the pincer complex undergoes N–H oxidative addition with ammonia and gives an isolable terminal amido Ir(III) mononuclear complex without suffering from N-H reductive elimination and subsequent Ir-(NH₃) complex formation. The concept of the electron-donating pincer ligand was further utilized in the design of the reactive iridium P,Si,P-¹⁰ and other similar pincer complexes.¹¹ In addition, Wolczanski et al. has demonstrated that early transition metal-mediated ammonia activation can be achieved with a trisiloxide tantalum(III) complex.¹²

Figure 2.1. Transition metal and main group molecules with N-H oxidative addition reactivity.

A well-characterized example of main group compound-mediated N-H oxidative addition was realized elegantly by Bertrand et al. with cyclic and acyclic (alkyl)(amino)carbenes **2.2** (Figure 2.1).¹³ With orthogonally-oriented frontier orbitals of proximate energy, the (alkyl)(amino)carbenes behave react with dihydrogen H-H and ammonia N-H bonds through oxidative addition. In line with the high-lying HOMO of the (alkyl)(amino)carbenes, the oxidative addition transition state develops asynchronously with a leading nucleophilic contribution from the carbene carbon to the

N-H hydrogen giving significant negative charged accrual on the nitrogen atom in the transition state. The complementary interaction of the electron-rich nitrogen and the electron-deficient carbene carbon contributes to a lesser extent in the activation process en route to tetravalent products. Complementarily to the nucleophilic mechanism in Bertrand's study in (alkyl)(amino)carbenes, Bielawski et al. demonstrated that N-H oxidative addition could also proceed by an electrophilic process on an electron-deficient di(amido)carbene.¹⁴ The di(amido)carbene in this study was designed to contain two electron-deficient amide N-substituents and consequently a lowerer LUMO energy.¹⁵ The resulting electronic structure enables ambiphilicity of this carbene in N-H oxidative addition; depending on the precise identity of amine substrate, either electrophilic or nucleophilic reactivity can be discerned with this species.

In related fashion to the carbenes, the N-H oxidative addition reactivity of heavier divalent group 14 molecules has also been demonstrated by Roesky,¹⁶ Power,¹⁷ and others.¹⁸ From the computational results, the oxidative addition transformations in these studies are most likely initiated by electrophilic interactions between the group 14 center and the lone pairs of ammonia nitrogen.

The prerequisites for successful N-H oxidative addition can be concluded from the above-mentioned studies in transition metal- and main group element-mediated transformations. Apart from a favorable reaction enthalpy, energetically and spatially accessible frontier orbitals are required for interaction with the N-H bonding and antibonding orbitals, and the consequent cleavage of N-H bonds. We envisioned that the

distorted O,N,O-phosphine **2.3** might exhibit N-H activation reactivity due to its electronic and steric properties (**Figure 2.1**).

2.3 Intermolecular N-H Oxidative Addition to the T-Shape O,N,O- σ^3 -Phosphorus Molecule

As discussed in Chapter 1, O,N,O-supported σ^3 -phosphorus compound **2.3** has a tricoordinating and electron-donating ligand which gives the molecule a planar T-shape geometry. As a result of this unusual geometry, the electronic structure of phosphine **2.3** contains an in-plane phosphorus-based lone pair in energetic proximity of the HOMO as well as a low lying LUMO with phosphorus-based $p\pi$ character. In effect, the electronic structure of phosphine **2.3** resembles the frontier electronic structure of carbenes and their heavier congeners. Distorted σ^3 -phosphorus compounds have demonstrated reversible bond activation reactivity as discussed in Chapter 1, suggesting potential for catalytic applications. Specifically, the catalytic transfer hydrogenation reactivity of T-shape phosphine **2.3**, which involves formal transfer of dihydrogen equivalent to and from phosphorus, has been reported by our laboratory.¹⁹ Although the mechanistic details in this system await a fuller accounting elsewhere, we hypothesized that this catalytic transformation might involve the oxidative addition of an N-H substrate to **2.3** (or its microscopic reverse – reductive elimination) at some stage of the catalytic cycle. In order to interrogate this hypothesis, we undertook a study of phosphine **2.3** with amine substrates including ammonia, alkyl and aryl amines.

Figure 2.2. Ammonia N-H oxidative addition to phosphine **2.3**.

The N-H oxidative addition reactivity of compound **2.3** was first tested by treating a solid sample of **2.3** with liquid ammonia (this experiment was conducted by Sean McCarthy). Gaseous NH_3 was condensed onto a solid sample of **2.3** at $-78\text{ }^\circ\text{C}$ (**Figure 2.2**). The mixture was stirred at $-78\text{ }^\circ\text{C}$ for 30 min, and then warmed to room temperature. The excess ammonia was evaporated under a nitrogen stream and the crude product was characterized by NMR spectroscopy. ${}^{31}\text{P}$ NMR showed a clean conversion from **2.3** (${}^{31}\text{P}$ NMR δ 187.7 ppm) to a single product with a ${}^{31}\text{P}$ NMR signal centered at δ -43.5 ppm, suggesting that a pentacoordinate phosphorus product **2.4** was obtained.²⁰ The observed ${}^{31}\text{P}$ NMR signal (**Figure 2.3 top**) presented as a large doublet with a coupling constant of $J = 812$ Hz, which is in the range of typical ${}^1J_{\text{P-H}}$ coupling and indicates the existence of a P-H bond. Based on previously reported correlations between P-H coupling and structure,²¹ the large P-H coupling constant suggested the existence of equatorial hydrogen substituent within a trigonal bipyramidal structure. Smaller ${}^3J_{\text{P-H}}$ coupling ($J = 1.1$ Hz) resulting from the vinylic ligand protons and ${}^2J_{\text{P-H}}$ coupling ($J = 10.2$ Hz) from the addend amido were also evident.

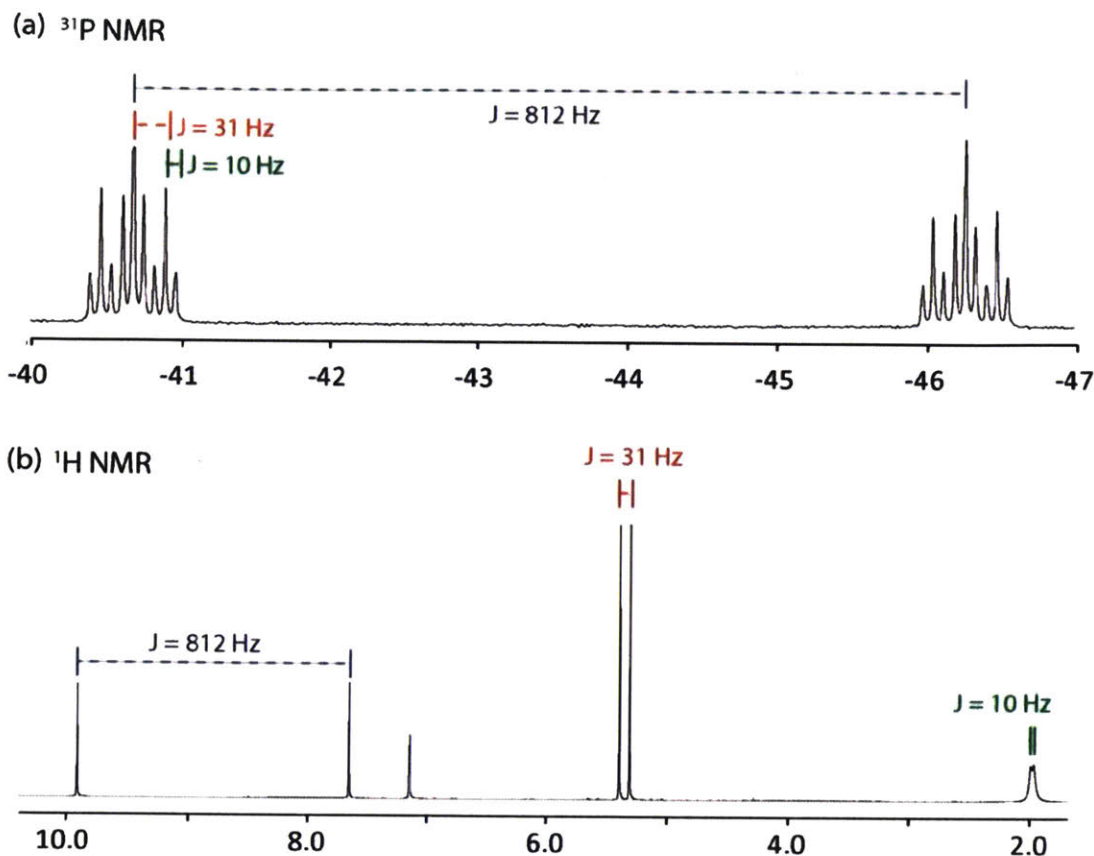

Figure 2.3. (a) Abridged annotated ^{31}P NMR spectrum for **2.4** in C_6D_6 . Units are ppm relative to H_3PO_4 . (b) Annotated ^1H NMR spectrum for **2.4** in C_6D_6 . An additional signal for $-\text{C}(\text{CH}_3)_3$ is found at δ 1.06 ppm. Units are ppm relative to Me_4Si . Reproduced with permission from *J. Am. Chem. Soc.* **2014**, *136*, 4640.

The phosphorus-based N-H oxidative addition is further supported by the complementary coupling in the ^1H NMR spectrum (**Figure 2.3 bottom**). A ^1H NMR doublet signal centered at δ 8.79 ppm with a very large coupling constant was observed and consistent with the P-H 1J coupling ($J = 812$ Hz). Furthermore, the infrared spectrum of the product showed a diagnostic 2374 cm^{-1} absorption which was in line with a P-H stretching mode. Two other IR absorptions appearing at 3516 and 3411 cm^{-1} could be

assigned to the symmetric and asymmetric stretching bands of the terminal -NH₂ group. The spectroscopic evidence strongly suggests a successful transformation from σ^3 -phosphorus molecule **2.3** to the σ^5 -phosphorus product **2.4** through N-H oxidative addition.

In addition to ammonia, compound **2.3** is also highly reactive toward the N-H bond of primary alkyl amines (**Figure 2.4 top**). When five equivalents of propylamine, isopropylamine, or benzylamine amine are added to a C₆D₆ solution of **2.3** in a sealed NMR tube at ambient temperature, complete consumption of **2.3** and quantitative conversion to hydrido amido phosphoranes **2.5a-c** is observed within 15 min by NMR spectroscopy (**2.5a**: δ -46.4 ppm, $^1J_{\text{P-H}} = 815$ Hz; **2.5b**: δ -47.1 ppm, $^1J_{\text{P-H}} = 819$ Hz; **2.5c**: δ -46.0 ppm, $^1J_{\text{P-H}} = 824$ Hz). During the course of the reaction, no intermediates are observed in ^1H or ^{31}P NMR spectra. Pure phosphorane products for ^1H NMR, mass spectrometry and elemental analysis are obtained by reacting exactly one equivalent of the amines with **2.3**, or by removing the excess amine with distillation. Aryl amines including *p*-anisidine, 2,4,6-trimethylaniline and 2,6-diisopropylaniline also undergo oxidative addition to compound **2.3**, but with a slower reaction rate than alkyl amines. At room temperature, five equivalents of *p*-anisidine are observed to react with **2.3** in C₆D₆ and yield hydrido anilido phosphorane **2.5d** (δ -48.7 ppm, $^1J_{\text{P-H}} = 831$ Hz) after 1 h. The reaction rate is further decreased with more sterically bulky anilines 2,4,6-trimethylaniline and 2,6-diisopropylaniline, but the transformations still give the corresponding adducts **2.5e** (δ -48.9 ppm, $^1J_{\text{P-H}} = 840$ Hz) and **2.5f** (δ -51.4 ppm, $^1J_{\text{P-H}} = 841$ Hz) respectively after 2 h at 55 °C (**Figure 2.4 bottom**). The arylaminophosphorane

products can be purified by neutral alumina column chromatography under nitrogen atmosphere.

Figure 2.4. N-H oxidative addition of alkyl and aryl amines to phosphine 2.3

Figure 2.5. N-H oxidative addition of aryl amines to phosphine **2.3** and the resulting phosphorane adducts and by-product.

Reacting compound **2.3** with other aryl amines results in more complex product mixtures. For example, treating 4-*tert*-butylaniline to **2.3** gives the expected phosphorane N-H oxidative addition adduct **2.6a** ($\delta -48.6 \text{ ppm}$, $^1J_{\text{P-H}} = 835 \text{ Hz}$) along with two P-H bearing phosphorus by-products ($\delta 14.1 \text{ ppm}$, $J = 667 \text{ Hz}$; $\delta 13.1 \text{ ppm}$, $^1J_{\text{P-H}} = 672 \text{ Hz}$). The by-products are tentatively assigned as ring-opened secondary iminophosphorane **2.6b** and secondary phosphine oxide **2.6c** (**Figure 2.5 top**). The formation of the by-products probably involves an intramolecular proton transfer from the amido N-H to one of the electron-rich axial oxygens, followed by enol-keto tautomerization and

intramolecular aza-Wittig reaction. Attempts to synthesize **2.6d** and **2.6e** by independent synthetic routes were not successful.

Figure 2.6. N-H oxidative addition of secondary amines to phosphine **2.3** and the resulting phosphorane adducts. Putative prototropic rearrangement product **2.7b** is depicted.

In contrast to the report by Arduengo,²² reactions of **2.3** and secondary amines also give N-H addition products, albeit along with ring-opened by-products. After stirring a mixture of solid **2.3** and condensed dimethylamine at $-78\text{ }^{\circ}\text{C}$ for 30 min followed by evaporation of the excess amine at room temperature, phosphorane **2.7a** ($\delta -36.5\text{ ppm}$, $^1J_{\text{P-H}} = 813\text{ Hz}$) can be detected as a minor product. The major product is observed at $\delta 130.1\text{ ppm}$ in ^{31}P NMR spectra as singlet signal, presumably corresponding to prototropic rearrangement product **2.7b** (**Figure 2.6 top**). Several other acyclic and cyclic secondary amines also undergo N-H oxidative addition with **2.3**, yielding comparable product and rearrangement product mixtures (**Figure 2.6 bottom**). At this stage, we attribute the reactivity difference between primary and secondary amines to steric effects that favor the less hindered σ^3 -product isomers over σ^5 - isomers.

2.4 Structure of the N-H Oxidative Addition Product

The stability of certain N-H addition products of **2.3** allows a more in-depth study of the structures of these compounds. Specifically, a solid sample of 2,4,6-trimethylaniline adduct **2.5e** can be obtained after filtration of its C_6D_6 solution through neutral alumina under nitrogen atmosphere. The resulting solid sample was then crystallized from a concentrated pentane solution to provide diffraction quality single crystals. The X-ray crystallography of this sample provided the structure of **2.5e** as shown in **Figure 2.7** (the X-ray diffraction experiments was conducted by Dr. Hemant Yennawar). In line the information obtained from ^{31}P NMR chemical shift and coupling

Figure 2.7. (Left) Molecular structure of **2.5e**. All hydrogen atoms on carbon are omitted for clarity. Thermal ellipsoids are shown at the 50% probability level. (Right) Top view of equatorial plane with schematic orbital representation of $n_N \rightarrow \sigma^* \text{P-N}$ interaction. Reproduced with permission from *J. Am. Chem. Soc.* **2014**, *136*, 4640.

constants, the phosphorane adopts an essentially trigonal bipyramidal structure at phosphorus with hydride and anilide group in equatorial positions. The O,N,O ligand retains a nearly planar arrangement spanning apical sites, with an O-P-O angle of $174.0(1)^\circ$. Given the higher phosphorus oxidation state, the P-O and P-N bond within the ligand framework are shorter in the phosphorane adduct than in T-shape phosphine **2.3**, as expected. Interestingly, the anilide nitrogen N(2) has a planar geometry and the coordination plane around N(2) oriented orthogonally to the phosphorus equatorial plane.

This structural arrangement suggests a possible stabilizing interaction between the N(2) lone pair and the P(1)-N(1) σ -antibonding orbital. This observation is in accordance with the established preference for π -donor substituents to occupy equatorial sites in pentavalent phosphorus molecules.²³ A computational NBO analysis provides additional support for the stabilizing hyperconjugative interaction.

2.5 Thermodynamic Analysis of the N-H Oxidative Addition Process

Thermodynamic studies of the reaction of **2.3** and *n*-propylamine has been conducted by Dr. Ji Woong Chang with isothermal titration calorimetry (ITC).²⁴ In a typical ITC experiment, a solution of **2.3** (1mM in C₆D₆, 1 mL total volume) was titrated with 6 μ L aliquots of a solution of *n*-propylamine (12.5 mM in C₆D₆) under a nitrogen atmosphere. An isotherm for the addition of *n*- propylamine to **2.3** (top) and the measured integrated heats (bottom) are shown in **Figure 2.8**. An independent binding sites model (red line in **Figure 2.8**) was utilized to confirm a 1:1 stoichiometry as expected for the addition reaction. This model also provides a reaction enthalpy (ΔH_{rxn}) of -10.6 ± 0.1 kcal/mol and an equilibrium constant (K_{eq}) of $(3.03 \pm 0.17) \times 10^4 \text{ M}^{-1}$.

Without reliable experimental P-N and P-H bond enthalpy data for comparable phosphoranes, computations were conducted to estimate bond strengths for comparison with the isothermal titration calorimetry results.²⁵ Using M06-2X/6-311++G(2d,2p) calculations, a reaction enthalpy (ΔH_{rxn}) of -7.4 kcal/mol is estimated, which is reasonably close to the experimental value of -10.6 ± 0.1 kcal/mol. Additionally, the P-H

Figure 2.8. Thermochemistry of N-H oxidative addition of *n*-propylamine to **2.3**. (Top) ITC thermogram at 25 °C in benzene. (Bottom) Plot of integrated heat evolved with fitted model. Reproduced with permission from *J. Am. Chem. Soc.* **2014**, *136*, 4640.

and P-N bond dissociation energies of dimethylamine adduct **2.7a** were calculated for comparison with those of similar previously reported phosphorus species (**Figure 2.9**). The calculated P-H bond dissociation energy $D_{\text{P-H}}$ of 70.6 kcal/mol is consistent with the previously reported results of hydrogen radical abstraction of hydridophosphoranes with thiyl radicals.²⁶ The calculated P-N bond dissociation energy $D_{\text{P-N}}$ (68.3 kcal/mol) is also close to the reported experimental values in both σ^3 -phosphorus ($D_{\text{P-N}} = 66.8 \pm 0.8$

kcal/mol in $\text{P}(\text{NEt}_2)_3$ ²⁷ and σ^3 -phosphorus ($D_{\text{P-N}} = 74.3$ kcal/mol in $(\text{Cl}_3\text{PNMe})_2$)²⁸ molecules.

Figure 2.9. M06-2X/6-311++G(2d,2p) P–H and P–N bond enthalpies. Reproduced with permission from *J. Am. Chem. Soc.* **2014**, *136*, 4640.

2.6 N-H Elimination and Amine Exchange of the Phosphorane Adducts

Since the experimental reaction enthalpy ΔH_{rxn} of -10.6 ± 0.1 kcal/mol of the N-H oxidative addition process is large enough to inhibit the reversed transformation under proper conditions, the N-H reductive elimination reactivity of the obtained phosphorane adduct was investigated. Due to the low sublimation temperature (40 °C) of ammonia adduct **2.4** under reduced pressure (1 mmHg), phosphorane adducts **2.5a** – **2.5c** which

contain smaller amido substituents were heated to 100 °C *in vacuo* in attempts to facilitate reductive elimination of amine and regenerate phosphine **2.3**. Unfortunately, no regeneration of compound **2.3** was observed in any of these experiments. Heating heavier adducts such as 2,4,6-trimethylaniline adduct **2.5e** to 100 °C at 1 mmHg also failed to give the elimination transformation, and further heating to higher temperatures leads to nonspecific decomposition.

Figure 2.10. N-H elimination of the phosphorane adducts.

Although no thermal N-H reductive elimination reactivity was observed for adducts **2.5**, treating phosphorane adducts **2.5** with Lewis acids gives the formal reductive elimination transformation (**Figure 2.10**). For example, adding five equivalents of boron trifluoride-diethyl etherate to a C₆D₆ solution of **2.4** results in the regeneration of **2.3** as the major product. The regeneration of **2.3** can also be observed in the reactions of **2.5a** and **2.5c** with boron trifluoride-diethyl etherate. Similarly, the reactions of aluminum trichloride and **2.4**, **2.5a** and **2.5c** result in conversion to **2.3** with little apparent decomposition.

In addition to Lewis acid-induced reductive elimination of amine, amine exchange was observed upon heating phosphorane adducts with an excess amount of an exogenous amine. In a sealed NMR tube, a C_6D_6 solution of 5 equiv of benzylamine and the propylamine adduct **2.5b** was heated at 80 °C for 24 h, during which time a complete conversion to benzylamine adduct **2.5c** was observed. In addition, the reverse reaction also gives complete conversion to **2.5b** when treating an excess amount of propylamine to **2.5c** under the same conditions (**Figure 2.11**). Although the mechanism of these exchanges has not been determined, the amine exchange of the phosphorane adducts is encouraging for the potential catalytic application of the N-H oxidative addition reactivity of **2.3**.

Figure 2.11. Amine exchange of the phosphorane adducts.

2.7 Mechanistic Analysis of the N-H Oxidative Addition Process²⁹

Four possible mechanisms can be considered for the N-H oxidative addition to T-shape phosphine **2.3** (**Figure 2.12**). In the first possible mechanism, a phosphorus-ligand

Figure 2.12. Possible Mechanisms for the N-H oxidative addition to phosphine **2.3**. (A) Ligand cooperative, (B) nucleophilic, (C) electrophilic, (D) concerted.

cooperative process (**Figure 2.12A**) proceeds through an initial N-H bond addition across the P-O bond and the resulting phosphacyclic intermediate. This phosphacyclic intermediate can then undergo an intramolecular O-H oxidative addition to yield the

phosphorane.³⁰ Metal-ligand cooperativity is generally accepted mechanism in bond activations by pincer-type transition metal species bearing similar O,N,O-ligand framework of **2.3**.^{7,31} Phosphorus-ligand cooperative mechanism appears to be a possible pathway due to the similar ligand structure with the pincer metal complexes and the detected phosphacyclic species in the oxidative addition of secondary amines. As discussed earlier in the chemistry of carbene-mediated N-H oxidative additions, stepwise mechanisms could involve either nucleophilic or electrophilic initiation steps. In an extreme case of the nucleophilic mechanism (**Figure 2.12B**), the nucleophilic phosphorus center might deprotonate the substrate N-H proton and generate a positively charged phosphorus center and an anionic amide. This ephemeral ion pair might then quickly collapse to the phosphorane product. However, with the low N-H bond acidity ($pK_a = \sim 35-40$)⁵ and the reported poor nucleophilicity of the phosphorus center of **2.3**,³² the nucleophilic mechanism seems unlikely for the N-H oxidative addition. The electrophilic mechanism (**Figure 2.3C**), on the other hand, is a more likely process because of the possible interaction of nucleophilic amine nitrogen HOMO with the distortion-induced low LUMO of T-shape phosphine **2.3**. In this electrophilic mechanism, the amine nitrogen might attack at the phosphorus center, producing a zwitterionic ammoniophosphoranide species with an acidified N-H proton. A following intramolecular proton transfer from nitrogen to phosphorus might then take place to give the formal oxidative addition product. In the last possible mechanism, a concerted three-centered mechanism (**Figure 2.12D**) involving the simultaneous cleavage of N-H bond and formation of the P-N and P-H bonds can be envisioned in analogy to well-established

reactivity in organometallic chemistry.² That said, this mechanism is more common for nonpolar substrates than for highly polarized bonds such as N-H. Therefore, the concerted mechanism is less likely to be involved in the N-H oxidative addition to phosphine **2.3** than other stepwise mechanisms.

Figure 2.13. Oxidative addition of *N,N*-dideuterobenzylamine (BnND_2) to **2.3** without incorporation of the isotopic label at the vinylic position of the O, N, O-ligand backbone. Note: **2.9** is a mixture of isotopologues due to incomplete deuterium labeling of BnND_2 .

2.7.1 Deuterium Labeling Study of N-H Oxidative Addition

Because of the observed phosphacyclic species in the oxidative addition of secondary amines (**Figure 2.6**), the phosphorus-ligand cooperative mechanism is considered a possible pathway for the N-H oxidative addition (**Figure 2.12A**). Due to the presumed enol intermediate and its rapid tautomerization in this mechanism, we

hypothesized that deuterium should be detected at the vinylic position of the O,N,O-supporting ligand in the P(V) adduct if a deuterium-labeled amine were used. Upon treatment of **2.3** to 5 equiv. of *N,N*-dideuterobenzylamine (BnND₂, 85% D) in C₆D₆, deuterium was detected only at phosphorus and nitrogen in the product **2.9** by ³¹P and ²H NMR (³¹P δ -47.0 ppm, ¹J_{P-D} = 126 Hz; ²H δ 8.95 ppm [1H, d, *J* = 824.7 Hz], 2.52 ppm [1H, s]) (**Figure 2.13**). Deuterium scrambling species (**2.8**) was not detected by ²H NMR spectroscopy, indicating that the enol intermediate and phosphorus-ligand cooperative mechanism is not involved. Instead, a process with interactions localized only to the phosphorus center is more likely in the initial step of the transformation. Vanka³³ and Sakaki³⁴ recently investigated the phosphorus-ligand cooperative mechanism with computational methods. In their studies, a low energy pathway to formal oxidative addition with ligand assistance mechanism is suggested. However, we believe that a mechanism involving no ligand participation remains more convincing based on the direct experimental evidence presented above.

2.7.2 UV-Vis Spectra of Compound **2.3** and **2.5a** for Kinetic Study

Due to the high reaction rate of the oxidative addition of *n*-propylamine to **2.3** (completed within 5 min. under pseudo-first order conditions), typical ¹H or ³¹P NMR spectroscopy is not suitable methods for kinetic study. Therefore, UV absorption spectra of **2.3** and the *n*-propylamine adduct **2.5a** were recorded. Compound **2.3** exhibits UV absorption features at 313 nm ($\epsilon = 7.9 \times 10^3 \text{ M}^{-1}\cdot\text{cm}^{-1}$), 220 nm ($\epsilon = 10.5 \times 10^3 \text{ M}^{-1}\cdot\text{cm}^{-1}$),

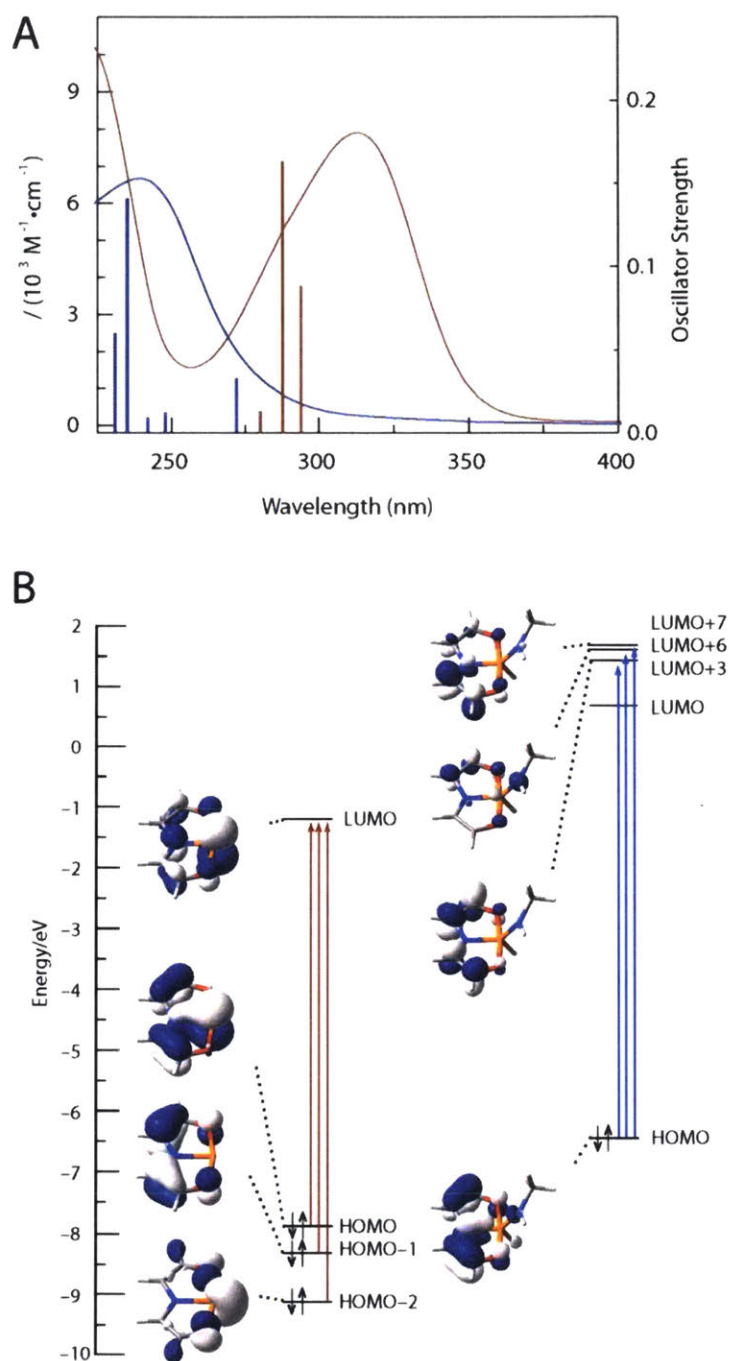

Figure 2.14. (A) Experimental absorption spectra for **2.3** (red line) and **2.5a** (blue line) superimposed with corresponding TDDFT (CAMB3LYP/6-311++G**) excited state transitions and oscillator strengths. (B) Molecular orbital isosurfaces and energies for models of **2.3** and **2.5a**. Reproduced with permission from *J. Am. Chem. Soc.* 2014, 136, 4640.

and 207 nm ($\epsilon = 10.5 \times 10^3 \text{ M}^{-1}\cdot\text{cm}^{-1}$) (**Figure 2.14A**, red line). The oxidative addition product **2.5a** has a hypsochromically shifted lowest energy absorption at 239 nm ($\epsilon = 6.7 \times 10^3 \text{ M}^{-1}\cdot\text{cm}^{-1}$; **Figure 2.14A**, blue line) with minimal overlap with the lowest energy band of **2.3** centered at 313 nm. As a result, the progress of the reaction between **2.3** and *n*-propylamine could be followed by monitoring the decay of the absorption at $\lambda = 313$ nm. The excitation energies of **3.1** and **3.2a** could also be simulated with time-dependent DFT (TDDFT) calculations (CAMB3LYP/6-311++G**). The results indicate that the low energy band is dominated by $\pi \rightarrow \pi^*$ and $n\text{P} \rightarrow \pi^*$ electronic transitions and are in good agreement with the experimental UV absorption spectrum (**Figure 2.14B**).

2.7.3 Determination of Reaction Order in Phosphine **2.3** in Pseudo-First Order Condition

In order to obtain the reaction molecularity of **2.3** in the N-H oxidative addition transformation, kinetic studies were conducted under pseudo-first order conditions. A solution of **2.3** in pentane (0.27 M) was added to a septum-equipped screw top quartz cuvette sealed under inert atmosphere. Upon injection of a large excess of *n*-propylamine (2250 equiv.) at 25 °C, the reaction was completed within 60 s. A collection of spectra in the range $225 \text{ nm} < \lambda < 400 \text{ nm}$ every 5 s for 60 s shows clean conversion from **2.3** to **2.5a** without detectable intermediates or side products. An isosbestic point was found at $\lambda = 272 \text{ nm}$ (**Figure 2.15 A**), indicating that no secondary reactions are involved in the transformation.³⁵ Another experiment run under the same conditions using benzene as the

solvent while monitoring the decay at $\lambda_{\text{max}} = 313$ nm provided data for plots of [2.3] vs. time and $\ln[2.3]$ vs. time spectra consistent with pseudo-first order decay (**Figure 2.15 B**).

Figure 2.15. (A) Time stacked UV absorption spectra indicating consumption of **2.3** and formation of **2.5a** with time. An isosbestic point occurs at $\lambda = 272$ nm. (B) Plot of [2.3] vs time monitored at $\lambda_{\text{max}} = 314$ nm. (Inset) Plot of $\ln[2.3]$ vs time with linear least-squares fit. Reproduced with permission from *J. Am. Chem. Soc.* **2014**, *136*, 4640.

2.7.4 Determination of Reaction Order in Amine in Pseudo-First Order Condition

With the constant concentration of **2.3** in benzene (0.27 mM) at 25 °C, the reactions were monitored with various *n*-propylamine concentration in pseudo-first order conditions (14-2222 equiv. of *n*-propylamine). Surprisingly, plots of the observed rate constant k_{obs} vs. $[\text{}^n\text{PrNH}_2]$ and k_{obs} vs. $[\text{}^n\text{PrNH}_2]^2$ are both non-linear, suggesting a reaction rate law which is neither first nor second order in amine. However, the plot of k_{obs} against $[\text{}^n\text{PrNH}_2]^3$ exhibits a linear relationship (**Figure 2.16**, $R^2 = 0.9996$), indicating that a third order reaction in amine and an unusual rate law with high overall molecularity:

$$-\frac{d[\mathbf{2.3}]}{dt} = k_{\text{obs}}[\mathbf{2.3}] = k[\mathbf{2.3}][\text{}^n\text{PrNH}_2]^3$$

Figure 2.16. Plot of k_{obs} vs. $[\text{}^n\text{PrNH}_2]^3$ with linear least-squares fit ($R^2 = 0.9996$). Inset: Expansion of low concentration data points. Reproduced with permission from *J. Am. Chem. Soc.* **2014**, *136*, 4640.

Figure 2.17. Eyring plot for kinetic data collected over the temperature range 10-70 °C. Reproduced with permission from *J. Am. Chem. Soc.* **2014**, *136*, 4640.

2.7.5 Eyring Plot for Activation Parameters

To find the activation enthalpy and entropy for the reaction, reactions between **2.3** (0.31 mM in benzene) and *n*-propylamine (2613 equiv.) were monitored at carried temperatures from 10 °C to 70 °C in 10 °C intervals. Interestingly, the observed reaction rate was found to decrease with increasing temperature. The Eyring plot derived from collected data provides activation parameters of $\Delta H^\ddagger = -0.8 \pm 0.4$ kcal/mol and $\Delta S^\ddagger = -72 \pm 2$ cal/mol·K (**Figure 2.17**). The highly negative activation entropy suggests the

existence of a high molecularity transition state which is agreement with the pseudo-first order experiments that a third order rate law in amine is involved. Although a reaction with a negative activation enthalpy is rare, examples of entropic-controlled transformations can be found in literature.³⁶

2.8 DFT Investigation of the N-H Oxidative Addition³⁷

The kinetic experiments discussed in the previous sections provide evidence for a high molecularity transition structure and large negative activation entropy, which confirm that a simple concerted mechanism for N-H oxidative addition to **2.3** is not involved in the transformation (**Figure 2.12 D**). To further assess the inviability of the concerted mechanism, DFT calculations were conducted to estimate the energetic barrier associated with the requisite three-centered transition structure (**Figure 2.18**). The calculated transition structure **TS-conc** (M062X, 6-311++G(2d,2p)) for the concerted N-H addition of methylamine to **2.3** was found to be significantly high in energy relative to the starting materials ($\Delta H^\ddagger = +50.1$ kcal/mol). The magnitude of this barrier can be understood in the context of the valence bond configurational mixing framework,³⁸ where the large singlet-triplet gap for **2.3** ($\Delta E_{ST} = 62.6$ kcal/mol) imposes a significant electronic barrier to direct, concerted oxidative addition. Together with the results from kinetics studies, these DFT calculations eliminate the concerted mechanism as a possible reaction pathway.

Figure 2.18. Concerted N-H oxidative addition to **2.3** with computed transition state structure. Computed enthalpies in parentheses in kcal/mol. Hydrogens and t-butyl methyl groups were omitted for clarity in TS-conc. Reproduced with permission from *J. Am. Chem. Soc.* **2014**, *136*, 4640.

DFT studies were also conducted for evaluating the proposed nucleophilic and electrophilic mechanisms (**Figure 2.12 B, C**). As discussed previously, the low N-H acidity of amines and the weak phosphorus nucleophilicity of **2.3** make the nucleophilic pathway (**Figure 2.12 B**) highly unlikely. Calculations performed on nucleophilic mechanism provide further confirmation that such a pathway is in fact energetically prohibitive. The relatively low energies of the occupied frontier orbitals of **2.3** (-7.5 , -7.9 , and -8.7 eV for HOMO, HOMO-1 and HOMO-2, respectively) as well as a large ionization potential ($\text{IP} = 6.4$ eV) suggest a high energetic barrier to phosphorus protonation. Additionally, a proton transfer from a single methylamine molecule is a prohibitively endothermic process ($\Delta H = 87.7$ kcal/mol). This enthalpy decreases if additional amine molecules are included in the calculation, but not nearly enough to make

amine deprotonation thermodynamically viable. Based on these DFT calculation results, the nucleophilic mechanism may also be excluded from further consideration.

Figure 2.19. Calculated stepwise electrophilic reaction pathway for the N-H oxidative addition of methylamine to **2.3** (M06-2X/6-311++G(2d,2p)), with enthalpies in parentheses and free energies in italics in kcal/mol. Hydrogens and *t*-butyl methyl groups we omitted for clarity on INT1 and INT2. Reproduced with permission from *J. Am. Chem. Soc.* **2014**, *136*, 4640.

Compared to the nucleophilic mechanism, DFT calculations suggest that an initial nucleophilic interaction is a viable pathway in the transformation. Compound **2.3** is calculated to have a low lying LUMO (-1.0 eV) and a reasonably favorable electron affinity (EA = -2.2 eV), making the electrophilic interaction of the phosphorus center of **2.3** and the amine nitrogen possible (**Figure 2.12 C**). Indeed, a computed pathway initiated by amine attack at phosphorus center of **2.3** is found to be significantly more energetically favorable than the nucleophilic pathway. Attempts to locate a zwitterionic P-N adduct intermediate on the energy surface failed when using only one molecule of amine. However, the addition of two additional amine molecules allowed for the location of an adduct (**INT1**) with a P-N bond distance of 1.97 Å (**Figure 2.19**). Compared to

Figure 2.20. Transition structures along the stepwise electrophilic pathway for N-H oxidative addition to **2.3** with computed metrics. Hydrogens and *t*-butyl methyl groups were omitted for clarity. Reproduced with permission from *J. Am. Chem. Soc.* **2014**, *136*, 4640.

starting material **2.3**, **INT1** is 3.8 kcal/mol lower in enthalpy but the hydrogen bonding cluster of three amine molecules makes **INT1** 10.1 kcal/mol higher than **2.3** on the free energy surface. Amine-assisted deprotonation of the phosphorus-bound amine via **TS1** gives **INT2** as a phosphoranide anion and an amine-solvated proton. The energetic barrier to this initial step is relatively small, with $\Delta H^\ddagger = -2.2$ kcal/mol and $\Delta G^\ddagger = 13.0$ kcal/mol for **TS1**. Interestingly, the bond lengths found for P-N (1.83 Å) and N-H (1.36 Å) in **TS1** (**Figure 2.20**) are close to those calculated in the much higher energy **TS-conc** in the concerted pathway, suggesting that a significant stabilization from the assistance of the two additional amine molecules. Once **INT2** is formed, the ammonium cation pair undergoes a reorientation for the following protonation of the phosphoranide via **TS2**.

TS2 has a modest activation enthalpy of $\Delta H^\ddagger = 2.4$ kcal/mol, and is the maximum on the free energy surface with $\Delta G^\ddagger = 18.4$ kcal/mol. Therefore, this proton transfer step is the rate determining step in the transformation and its relatively high activation barrier is resulted from the entropic penalty associated with the organization of the amine hydrogen bonding network.

To conclude, the computed phosphorus-based electrophilic pathway for the N-H oxidative addition is consistent with the experimental kinetics study. From the calculation results, two additional amine molecules are needed for stabilizing the resulting positively charged species from the initial electrophilic interaction from phosphorus to amine, in good agreement with the observed third order molecularity of amine. Additionally, the highly ordered transition state structure rationalizes the entropy-dominated rate determining step derived from the Eyring plot. Although the calculated activation enthalpy is slightly positive ($\Delta H^\ddagger_{\text{calc}} = 2.4$ kcal/mol), this value is still reasonably close to the experimental value ($\Delta H^\ddagger_{\text{expt}} = -0.8 \pm 0.4$ kcal/mol).

2.9 Conclusion and Outlook

A rare example of well-characterized intermolecular N-H oxidative addition to a geometrically distorted phosphorus (III) center is presented in this chapter. The reactions of the T-shape phosphine and ammonia, alkyl and aryl amines through an unusual phosphorus-based electrophilic mechanism give stable hydrido amido phosphorane products. The stability of phosphorane products allows in-depth characterization via

NMR and X-ray diffraction for unambiguous confirmation of their identities and geometric structures. In addition to being a fundamentally interesting and largely unprecedented reaction, the discovered oxidative addition reaction provides important support for our hypothesis that geometry of phosphorus molecules can exert a strong influence on reactivity.

The experimental and computational results provide strong evidence for a highly unusual entropy-controlled mechanism for N-H oxidative addition to the T-shape phosphine. The mechanism involves a nucleophilic attack of amine to the tricoordinate phosphorus center followed by a rate determining proton transfer assisted by two additional amine molecules to give the product phosphorane. The direct N-H reductive elimination from the hydrido amido phosphorane was not observed even under forcing conditions, and the lack the reversibility of the transformation can be rationalized by the established reaction mechanism. Due to the necessity of proton shuttling by exogenous amine in the N-H oxidative addition, the principle of microscopic requires that reversed elimination reaction proceeds with the same pathway. Therefore, amine exchange of hydrido amido phosphorane can be achieved in the presence of exogenous amine while the reductive elimination from the isolated adducts is mechanistically prohibited. The understanding of this mechanism and the factors influencing this non-traditional P(III) reactivity should help future work both in leveraging the reactivity of the T-shape phosphine toward synthetically valuable transformations and more importantly, in the rational design of novel P(III) compounds capable of unprecedented reactivity.

2.10 Experimental

General Materials and Methods

All reagents were purchased through Sigma-Aldrich, Alfa Aesar, ACROS, TCI, or Oakwood Chemical, and used as received unless otherwise noted. Diethyl ether (Et₂O), methylene chloride (CH₂Cl₂), tetrahydrofuran (THF), and pentane were dried according to the method of Grubbs³⁹ as modified by Bergman⁴⁰ using a Glass Contour Solvent Purification System. Propylamine (99%) was purchased from Alfa Aesar and purified by vacuum distillation from zinc dust prior to use. Isopropylamine (≥99.5%) was purchased from Aldrich and purified by vacuum distillation from zinc dust. Benzylamine (98%) was purchased from Alfa Aesar and purified by vacuum distillation from zinc dust. 2,4,6-Trimethylaniline (98%) was purchased from Aldrich and purified by vacuum distillation from potassium hydroxide. 2,6-Diisopropylaniline (90+%) was purchased from Alfa Aesar and purified by vacuum distillation from potassium hydroxide. p-Anisidine (≥99%) was purchased from Aldrich and purified by recrystallization from ethanol. All glassware was oven-dried at 120 °C prior to use. All reactions were carried under dry nitrogen atmosphere (Schlenk line or glovebox) unless otherwise noted. NMR spectra were recorded on a Bruker AV-360 (360MHz), a Bruker AV-400 (400 MHz), a Bruker AV-500 (500MHz) or a VARIAN Inova-500 (500MHz) spectrometer. ¹H NMR chemical shifts are given in ppm with respect to solvent residual peak (C₆D₆, δ 7.16 ppm; CDCl₃, δ 7.26 ppm; CD₂Cl₂, δ 5.32 ppm), ¹³C{¹H} NMR shifts are given in ppm with respect to CDCl₃ (δ 77.16 ppm), C₆D₆ (δ 128.06 ppm) or CD₂Cl₂ (δ 53.84 ppm). Coupling constants

are reported as *J*-values in Hz. High resolution EI and ESI mass spectra were obtained from the Mass Spectrometry Laboratory at the School of Chemical Sciences, University of Illinois at Urbana-Champaign.

Synthetic Procedures and Characterization Data

Phosphorus compound **2.3** was prepared by minor modification of the literature method according to the following sequence²² (**Figure 2.21**):

Figure 2.21. Multistep synthesis of phosphine **2.3**.

To a ethyl ether of solution (80 ml) of pinacolone (50.0 g, 499 mmol) was added several drops of bromine at ambient temperature. The orange solution became colorless and was subsequently cooled in an ice bath. Bromine (26 mL, 499 mmol) was added dropwise over an hour, maintaining the internal temperature below 10 °C. The reaction mixture was stirred an additional 30 min, then 200 mL of water was

added and stirred for 15 min. The reaction mixture was warmed to room temperature and treated with solid sodium bicarbonate (42 g, 499 mmol) and the resulting phasic layers were separated. The ether layer was washed with brine (2x50 mL), dried (Na₂SO₄), and concentrated *in vacuo*. Purification by vacuum distillation yielded **S2.1** as a light yellow oil (78 g, 87%). ¹H NMR (300 MHz, CDCl₃): δ 4.18 (2H, s), 1.23 (9H, s) ppm.

To a toluene (900 ml) solution of **S2.1** (70.3 g, 393 mmol) was added benzylamine (43 mL, 339 mmol) in one portion. The reaction mixture was stirred at 80 °C for 48 h, during which time a voluminous white solid precipitated. The solid was collected on a Buchner funnel, washed with water (2x100 mL), and recrystallized in ethanol to give **S2.2** as a white crystalline solid (62 g, 82%). ¹H NMR (360 MHz, CDCl₃): δ 7.66 (2H, m), 7.46 (3H, m), 4.94 (2H, m), 4.72 (4H, m), 1.14 (18H, s) ppm.

To a suspension of **S2.2** (60.0 g, 150 mmol) in nitrogen-sparged methanol (500 mL) was added 10% palladium on carbon (600 mg, 0.6 mmol). The atmosphere was exchanged for hydrogen via three evacuation/backfill cycles. The heterogeneous mixture was stirred under H₂ (1 atm) for 24 hours. The reaction mixture was then filtered over celite and the filtrate was concentrated. Recrystallization of the crude solid product in ethanol gave **S2.3** as a white solid (40.5 g, 90%). ¹H NMR (360 MHz, CDCl₃): δ 4.31 (4H, s), 1.23 (18H, s) ppm.

A mixture of **S2.3** (30.0 g, 102 mmol), water (400 mL) and dichloromethane (300 mL) was cooled in an ice bath. An aqueous solution of tribasic potassium phosphate (26.0 g, 122 mmol, 270 mL, 0.46 M) was added dropwise over 30 minutes, then the solution was stirred for an additional 2 hours in an ice bath. The aqueous layer was extracted with dichloromethane (3x100 mL), then the dichloromethane extracts were washed with water (3x200 mL). The organic layer was dried (Na₂SO₄) and concentrated *in vacuo* to give **S2.4** as a yellow solid (16.0 g, 90%), which was stored at -30 °C prior to further use. ¹H NMR (400 MHz, CDCl₃): δ 3.62 (4H, s), 2.83 (1H, br s), 1.15 (18H, s) ppm.

At -78 °C, a pentane solution (150 mL) of phosphorus (III) chloride (4.1 mL, 47 mmol) under nitrogen was added **S2.4** (10.0 g, 48 mmol) in pentane (130 mL) dropwise. After a pentane solution (100 mL) of triethylamine (20.5 mL, 147 mmol) was added dropwise, the resulting mixture was stirred at -78 °C for 4 hours. The mixture was then warmed to room temperature and stirred for an additional 2 hours. The reaction mixture was concentrated to a residue *in vacuo* and transferred to a glovebox. The crude reaction residue was then triturated with pentane (200 mL) and filtered over celite. The filtrate was concentrated to give crude **2.3** and further recrystallization from pentane at -35 °C gives pure **1** as a yellow solid (4.6 g, 73%). ¹H NMR (400 MHz, CDCl₃): δ 7.40 (2H, d, *J*=9.6 Hz), 1.27 (18H, s) ppm. ³¹P{¹H} NMR (145 MHz, CDCl₃): 187.7 ppm.

A nitrogen-flushed 25 mL round bottom flask equipped with a magnetic stirrer was charged with **2.3** (200 mg, 0.83 mmol). Ammonia (ca. 5 mL) was condensed into the flask cooled to $-78\text{ }^{\circ}\text{C}$. The suspension was stirred at $-78\text{ }^{\circ}\text{C}$ for 30 min, and then warmed to room temperature to remove the excess ammonia, yielding **2.4** as a yellow solid (214 mg, 0.83 mmol, quantitative yield). ^1H NMR (360 MHz, C_6D_6) δ 8.79 (1H, d, $J = 812$ Hz), 5.35 (2H, d, $J = 31$ Hz), 1.98 (2H, d, $J = 10$ Hz), 1.12 (18H, s) ppm. ^{13}C NMR (90 MHz, C_6D_6): δ 149.6 (d, $J = 3.6$ Hz), 100.4 (d, $J = 16.3$ Hz), 31.9 (d, $J = 3.6$ Hz), 27.7 (s) ppm. ^{31}P NMR (145 MHz, C_6D_6): δ -43.5 (dtq, $J = 813, 31, 10$ Hz) ppm. HRMS (EI) calcd for $[\text{C}_{12}\text{H}_{23}\text{N}_2\text{O}_2\text{P}]^+$, 258.14972; found, 258.15011. FT-IR (ATR): 3516, 3411, 3128, 2959, 2374, 1655, 1213 cm^{-1} . Anal. Calcd (found) for $\text{C}_{12}\text{H}_{23}\text{N}_2\text{O}_2\text{P}$: C, 55.83 (55.68); H, 8.98 (8.71); N, 10.85 (10.51); P, 12.00 (12.35).

To a solution of *n*-propylamine (85.0 μL , 1.05 mmol) in d_6 -benzene (2 mL) was added **2.3** (50 mg, 0.21 mmol). The solution was transferred to a sealed J. Young NMR tube and allowed to stand at room temperature for 20 min. The volatile components were removed *in vacuo* to yield **2.5a** as a yellow solid (62 mg, 0.21 mmol, quantitative by NMR). ^1H NMR (300 MHz, C_6D_6) δ 8.87 (1H, d, $J = 821.3$ Hz), 5.42 (2H, d, $J = 30.6$ Hz), 2.82 (2H, qt, $J = 7.3, 7.1$ Hz), 2.22 (1H, dt, $J = 12.5, 5.5$), 1.24 (2H, ddt, $J = 12.5, 7.1, 5.5$ Hz), 1.16 (18H, s), 0.72 (3H, t, $J = 7.3$ Hz) ppm. ^{31}P NMR (146 MHz, C_6D_6): δ -45.85 (dtq, $J = 821.3, 30.6, 12.5$ Hz) ppm. ^{13}C NMR (91 MHz, C_6D_6): δ 149.4 (d, $J = 3.6$ Hz),

100.7 (d, $J = 16.3$ Hz), 43.5 (s), 32.1 (d, $J = 2.6$ Hz), 27.8 (s), 26.4 (d, $J = 3.3$ Hz), 11.2 (s) ppm. HRMS (ESI) calc'd for $[C_{15}H_{29}N_2O_2P]^+$: 301.19667; found: 301.19580. FT-IR (ATR): 3436, 2959, 2871, 2372, 1655, 1215 cm^{-1} .

To a solution of isopropylamine (85.0 μ L, 1.05 mmol) in d_6 -benzene (2 mL) was added **2.3** (50 mg, 0.21 mmol). The solution was placed in a sealed J. Young NMR tube and allowed to stand at room temperature for 20 min. The volatile components were removed *in vacuo* to yield **2.5b** (62 mg, 0.21 mmol, quantitative yield by NMR). Alternatively, compound **2.3** was dissolved in neat isopropylamine (2 mL) at ambient temperature for 1 h. Removal of the residual isopropylamine *in vacuo* yielded **2.5b** as a yellow solid. 1H NMR (360 MHz, C_6D_6) δ 8.92 (1H, d, $J = 819.0$ Hz), 5.43 (2H, d, $J = 30.6$ Hz), 3.67 (1H, d septet d, $J = 8.7, 6.3, 5.9$ Hz), 2.14 (1H, dd, $J = 11.2, 8.7$ Hz) 1.17 (18H, s), 0.94 (6H, d, $J = 6.3$ Hz) ppm. ^{31}P NMR (146 MHz, C_6D_6): δ -47.0 (dtdd, $J = 819.4, 30.6, 11.2, 5.9$ Hz) ppm. ^{13}C NMR (91 MHz, C_6D_6): δ 149.3 (d, $J = 3.8$ Hz), 100.5 (d, $J = 16.4$ Hz), 42.9 (s), 31.9 (d, $J = 2.7$ Hz), 27.6 (s), 25.9 (d, $J = 5.6$ Hz) ppm. HRMS (ESI) calc'd for $[C_{15}H_{29}N_2O_2P]^+$: 301.19667; found: 301.19642. Anal. Calcd (Found) for $C_{15}H_{29}N_2O_2P$: C, 60.01 (59.61); H, 9.74 (9.68); N, 9.33 (9.26); P, 10.32 (10.83).

To a solution of benzylamine (113.5 μL , 1.05 mmol) in d_6 -benzene (2 mL) was added **2.3** (50 mg, 0.21 mmol). The solution was transferred to a sealed J. Young NMR tube and allowed to stand at room temperature for 2 h. The volatile components were removed *in vacuo* to yield **2.5c** (72 mg, 0.21 mmol, quantitative yield by NMR). Alternatively, compound **2.3** was dissolved in neat benzylamine (2 mL) at ambient temperature for 1 h. Removal of residual benzylamine *in vacuo*, yielded **2.5c** as a yellow solid. ^1H NMR (360 MHz, C_6D_6) δ 8.95 (1H, d, $J = 824.7$ Hz), 7.18 (2H, dt, $J = 7.0, 6.0$ Hz), 7.11 (2H, t, $J = 6.0$ Hz), 7.01 (1H, t, $J = 7.0$ Hz), 5.44 (2H, d, $J = 30.8$ Hz), 4.12 (2H, dd, $J = 12.7, 7.0$ Hz), 2.52 (1H, dd, $J = 13.3, 6.95$ Hz), 1.09 (18H, s) ppm. ^{31}P NMR (146 MHz, C_6D_6): δ -46.4 (dtd, $J = 823.6, 30.8, 13.3, 12.7$ Hz) ppm. ^{13}C NMR (91 MHz, C_6D_6): δ 149.7 (d, $J = 4.3$ Hz), 142.3 (d, $J = 4.5$ Hz), 128.5 (s), 126.9 (s), 126.8 (s), 100.5 (d, $J = 16.6$), 45.7 (s), 32.1 (d, $J = 3.1$ Hz), 27.7 (s) ppm. HRMS (EI) calc'd for $[\text{C}_{19}\text{H}_{29}\text{N}_2\text{O}_2\text{P}]^+$: 348.19667; found: 348.19721.

To a solution of *p*-anisidine (258 mg, 2.10 mmol) in d_6 -benzene (2 mL) was added **2.3** (50 mg, 0.21 mmol). The solution was transferred to a sealed J. Young NMR tube and allowed to stand at room temperature for 12 h. Removal of the volatile components *in vacuo*, and purification by column chromatography under nitrogen atmosphere (neutral alumina, 12:1 pentane: CH_2Cl_2) yielded **2.5d** as an unstable solid. ^1H

NMR (360 MHz, C₆D₆) δ 9.08 (1H, d, *J* = 831.0 Hz), 6.92 (2H, d, *J* = 8.5 Hz), 6.65 (2H, d, *J* = 8.5 Hz), 5.45 (2H, d, *J* = 31.0 Hz), 4.14 (1H, d, *J* = 11.2 Hz), 3.26 (3H, s) 1.04 (18H, s) ppm. ³¹P NMR (146 MHz, C₆D₆): δ -48.5 (dtd, *J* = 831.4, 31.5, 11.2 Hz) ppm. Instability precluded further characterization.

To a solution of 2,4,6-trimethylaniline (106 mg, 0.78 mmol) in d₆-benzene (2 mL) was added **2.3** (200 mg, 0.83 mmol). The solution was transferred to a sealed J. Young NMR tube and heated to 55°C for 2 h. Removal of the volatile components *in vacuo*, and purification by column chromatography under nitrogen atmosphere (neutral alumina, 12:1 pentane:CH₂Cl₂) yielded **2.5e** as an off-white solid (110 mg, 35% yield). ¹H NMR (360 MHz, C₆D₆) δ 9.04 (1H, d, *J* = 839.0 Hz), 6.72 (2H, s), 5.41 (2H, d, *J* = 30.7 Hz), 3.43 (1H, d, *J* = 10.1 Hz), 2.27 (6H, s), 2.13 (3H, s), 0.97 (18H, s) ppm. ³¹P NMR (146 MHz, C₆D₆): δ -48.7 (dtd, *J* = 839.3, 30.5, 10.2 Hz) ppm. ¹³C NMR (91 MHz, C₆D₆): δ 150.0 (d, *J* = 4.0 Hz), 137.0 (d, *J* = 3.2 Hz), 135.5 (d, *J* = 3.7 Hz), 134.6 (d, *J* = 2.0 Hz), 100.2 (d, *J* = 15.5 Hz), 128.4 (s), 31.8 (d, *J* = 2.6 Hz), 27.3 (s), 20.7 (s), 19.0 (s) ppm. HRMS (ESI) calc'd for [C₂₁H₃₃N₂O₂P]⁺: 376.2358; found: 377.2351. Anal. Calcd (Found) for C₂₁H₃₃N₂O₂P: C, 67.04 (67.32); H, 8.84 (8.66); N, 7.45 (7.49); P, 8.23 (8.18).

2.5f

To a solution of 2,6-diisopropylaniline (183 mg, 1.05 mmol) in d_6 -benzene (2 mL) was added **2.3** (50 mg, 0.21 mmol). The solution was transferred to a sealed J. Young NMR tube and heated to 40°C for 16 h. Removal of the volatile components *in vacuo*, and purification by column chromatography under nitrogen atmosphere (neutral alumina, 12:1 pentane:CH₂Cl₂) yielded **2.5f** as an off-white solid (45 mg, 52% yield). ¹H NMR (300 MHz, C₆D₆) δ 9.11 (1H, d, $J = 840.8$ Hz), 7.03-7.16 (3H, m), 5.41 (2H, d, $J = 30.7$ Hz), 3.75 (1H, d, $J = 9.7$ Hz), 3.57-3.66 (2H, m), 1.20-1.37 (6H, m), 1.15 (6H, d, $J = 6.8$ Hz), 0.95 (18H, s) ppm. ³¹P NMR (146 MHz, C₆D₆): δ -48.5 (dtd, $J = 840.8, 30.6, 9.7$ Hz) ppm. ¹³C NMR (91 MHz, C₆D₆): δ 150.1 (d, $J = 4.0$ Hz), 147.7 (d, $J = 3.2$ Hz), 127.0 (d, $J = 2.0$ Hz), 123.4 (s), 123.1 (s), 100.5 (d, $J = 15$ Hz), 31.9 (s), 28.8 (s), 28.1 (d, $J = 9.2$ Hz), 27.3(s), 22.5(s) ppm. Anal. Calcd (Found) for C₂₄H₃₉N₂O₂P: C, 68.87 (68.95); H, 9.39 (9.10); N, 6.69 (6.72); P, 7.40 (7.57).

2.6a

To a solution of 4-*tert*-butylaniline (0.33 mL, 2.10 mmol) in d_6 -benzene (2 mL) was added **2.3** (50 mg, 0.21 mmol). The solution was transferred to a sealed J. Young NMR tube and allowed to stand at room temperature for 12 h. Removal of the volatile components *in vacuo* yielded **2.6a** as an unstable solid (~50% conversion by ³¹P NMR). ¹H NMR (360 MHz, C₆D₆) δ 9.08 (1H, d, $J = 831.0$ Hz), 6.92 (2H, d, $J = 8.5$ Hz), 6.65 (2H, d, $J = 8.5$ Hz), 5.45 (2H, d, $J = 31.0$ Hz), 4.14 (1H, d, $J = 11.2$ Hz), 3.26 (3H, s) 1.04

(18H, s) ppm. ^{31}P NMR (146 MHz, C_6D_6): δ -48.6 (d, $J = 835$ Hz) ppm. Instability precluded further characterization.

A nitrogen-flushed 25 mL round bottom flask equipped with a magnetic stirrer was charged with **2.3** (200 mg, 0.83 mmol). Dimethylamine (ca. 5 mL) was passed through an anhydrous calcium sulfate column and condensed into the flask cooled to -78 °C. The suspension was stirred at -78 °C for 30 min, and then warmed to room temperature to remove the excess dimethylamine, yielding a mixture of crude **2.7a** and **2.7b** as a yellow solid (~80% total by ^{31}P NMR). ^{31}P NMR (145 MHz, C_6D_6): δ -36.5 (d, $J = 813$ Hz) (**2.7a**); 130.1 (s) (**2.7b**) ppm. Instability precluded further characterization.

General procedure for Lewis acid-induced reductive elimination from adducts **2.4**.

To a solution of **2.4** (0.21 mmol) in d_6 -benzene (2 mL) was added either boron trifluoride-diethyl etherate (0.13 mL, 1.05 mmol) or anhydrous aluminum trichloride (14 mg, 1.05 mmol). The solution was transferred to a sealed J. Young NMR tube and allowed to stand at room temperature for 30 m. In all cases, **2.3** was the only phosphorus-containing species detected by ^{31}P NMR after 30 m.

To a solution of *N,N*-dideuterobenzylamine (68.1 μL , 0.63 mmol, 83% deuteration) in d_6 -benzene (2 mL) was added **2.3** (50 mg, 0.21 mmol). The solution was transferred to a sealed J. Young NMR tube and allowed to stand at room temperature for 2 h. The volatile components were removed in vacuo to yield **2.9** (72 mg, 0.21 mmol, 65% deuteration). ^1H NMR (360 MHz, C_6D_6): δ 7.18 (2H, dt, $J = 7.0, 6.0$ Hz), 7.11 (2H, t, $J = 6.0$ Hz), 7.01 (1H, t, $J = 7.0$ Hz), 5.44 (2H, d, $J = 30.8$ Hz), 4.12 (2H, dd, $J = 12.7, 7.0$ Hz), 1.09 (18H, s) ppm. ^{31}P NMR (146 MHz, C_6D_6): **2.9a** (**2.3** \cdot [D][NDBn]) δ -47.0 (ttd, $J = 125.8, 30.8, 12.6$ Hz), **2.9b** (**2.3** \cdot [D][NHBn]) (δ -46.87, ttttd, $J = 125.8, 30.8, 12.6, 13.3$ Hz); **2.9c** (**2.3** \cdot [H][NDBn]) (δ -46.50, dtt, $J = 824.7, 30.8, 12.6$ Hz); **2.9d** (**2.3** \cdot [H][NHBn]) (δ -46.41, dttd, $J = 824.7, 30.8, 12.6, 13.3$ Hz), ppm. ^{13}C NMR (91 MHz, C_6D_6): δ 149.7 (d, $J = 4.3$ Hz), 142.3 (s), 128.5 (s), 126.9 (s), 126.8 (s), 100.5 (d, $J = 16.6$), 45.7 (s), 32.1 (d, $J = 3.1$ Hz), 27.7 (s) ppm. ^2H NMR (61 MHz, C_6D_6): δ 8.95 (1H, d, $J = 824.7$ Hz), 2.52 (1H, s) ppm.

Kinetics Experimental Procedures

All kinetics experiments were conducted on the oxidative addition reaction of *n*-propylamine to **2.3** (Figure 2.22). Compound **2.3** was recrystallized from pentane three times then stored in a nitrogen-filled glovebox before use. *n*-Propylamine was distilled twice from zinc dust then stored in a nitrogen-filled glovebox before use. Benzene and

pentane were dried by passage over an activated alumina column, stirring overnight over a mixture of K_2CO_3 and molecular sieves, and filtration through basic alumina.

Figure 2.22. Oxidative addition of *n*-propylamine to **2.3**.

Time-stacked UV-vis spectra (Figure 2.15 A). Measurements were performed on a Hewlett-Packard 8453 spectrophotometer with a Hewlett-Packard 8909DA peltier-thermostatted cuvette holder. A stock solution of compound **2.3** (3 mL, 0.27 mM in pentane) was added to a screw-top quartz cuvette (1 cm pathlength) fitted with a threaded septum. An initial UV-vis absorbance spectrum ($225\text{ nm} < \lambda < 400\text{ nm}$) was recorded. *n*-Propylamine (0.2 mL, 2250 equiv.) was then added via syringe and spectra were collected at 5 s intervals over the course of 1 min. The spectra (Figure 3.4) show the consumption of **1** ($\lambda_{max} = 313\text{ nm}$) and an increase in absorbance at lower wavelengths consistent with the formation of **2.5a** (the absorbance maximum of **2.5a** ($\lambda_{max} = 239\text{ nm}$) is obscured by the tail from the excess $nPrNH_2$). An isosbestic point is evident at $\lambda = 272\text{ nm}$.

Pseudo-first order kinetics (Figure 2.15 B). Measurements were performed on a Hitachi Digilab U-3010 spectrophotometer equipped with a cuvette holder thermostatted

by a VWR 1140S water circulator. A stock solution of compound **2.3** (3 mL, 0.31 mM in benzene) was added to a screw-top quartz cuvette (1 cm pathlength) fitted with a threaded septum. The cuvette was placed in the temperature controlled spectrometer cell holder (25 °C) and allowed to thermally equilibrate for 10 min. Absorbance data were then collected at $\lambda = 314$ nm for ca. 15 seconds to establish a $t = 0$ baseline value. *n*-propylamine (0.2 mL, 2250 equiv.) was then added via syringe and spectra were collected at 0.2 s intervals over the course of 500 s.

Determination of reaction order in amine (Figure 2.16). Measurements were performed on a Hitachi Digilab U-3010 spectrophotometer equipped with a cuvette holder thermostatted by a VWR 1140S water circulator. A stock solution of compound **2.3** (3 mL, 0.31 mM in benzene) was added to a screw-top quartz cuvette (1 cm pathlength) fitted with a threaded septum. The cuvette was placed in the temperature controlled spectrometer cell holder (25 °C) and allowed to thermally equilibrate for 10 min. Absorbance data were then collected at $\lambda = 314$ nm for ca. 15 seconds to establish a $t = 0$ baseline value. *n*-Propylamine solutions of varying concentrations (0.2 mL, 0.06 to 10.33 M, 14 to 2222 equiv.) were then added via syringe and spectra were collected at 0.2 s intervals over the course of 500 s. The observed pseudo-first order rate constant (k_{obs}) was extracted from an average of three independent runs at each concentration. The raw data is available in Appendix A.

Eyring kinetics (Figure 2.17). Measurements were performed on a Hitachi Digilab U-3010 spectrophotometer equipped with a cuvette holder thermostatted by a VWR 1140S water circulator. A stock solution of compound **2.3** (3 mL, 0.31 mM in benzene) was added to a screw-top quartz cuvette (1 cm pathlength) fitted with a threaded septum. The cuvette was placed in the temperature controlled spectrometer cell holder and allowed to thermally equilibrate for 10 min to a series of temperatures (10 to 70 °C). Absorbance data were then collected at $\lambda = 314$ nm for ca. 15 seconds to establish a $t = 0$ baseline value. *n*-propylamine (0.2 mL, 2613 equiv.) was then added via syringe and spectra were collected at 0.2 s intervals over the course of 500 s. The observed pseudo-first order rate constant (k_{obs}) was extracted from an average of three to six independent runs at each temperature. The raw data is available in Appendix A.

**Chapter Three. Phosphorus-ligand Cooperative B-H Activation and
Catalytic Hydroboration by a C_s - Symmetric N,N,N-
 σ^3 -Phosphorus Molecule**

A significant portion of the work described in this chapter has been published in:

Lin, Y.-C.; Hatzakis, E.; McCarthy, S. M.; Reichl, K. D.; Lai, T.-Y.; Yennawar, H. P.; Radosevich, A. T. *J. Am. Chem. Soc.* **2017**, *139*, 6008.

Chapter Three

Phosphorus-ligand Cooperative B-H Activation and Catalytic Hydroboration by a C_s -Symmetric N,N,N- σ^3 -Phosphorus Molecule

The investigation of the N-H oxidative addition reactivity of the T-shape O,N,O-phosphine discussed in the previous chapter offers valuable insight into the impact of geometric distortion on electronic structure and reactivity of σ^3 -phosphorus molecules. The study demonstrates significant agreement with our hypothesis that a phosphine with low nucleophilicity and electrophilic reactivity can be obtained as its molecular symmetry transforms from traditional pyramidal to planar. However, it remained unclear whether the unique reactivity is limited only to the planar geometry or can also be realized with other geometries. As exemplified in Chapter 1 with simpler molecules, we envisioned that similar or more drastic electronic and reactivity changes might be associated with other modes of geometry distortion. Since the O,N,O-chelating framework appeared to be essential to the formation of the planar structure, substitution of chelating atoms may offer opportunities in creating phosphines with novel molecular structures and reactivity. To address these questions, our group has recently designed an N,N,N-chelated phosphine bicycle with C_s -symmetry and demonstrated its reactivity in reversible O-H and N-H activation.¹ Inspired by our study of the C_s -symmetric N,N,N-phosphine, this chapter will focus on the studies of distortion-induced B-H activation

reactivity of the C_s -symmetric N,N,N-phosphine and its application in catalytic hydroboration.

3.1 Geometry, Electronic Structure and Reactivity of the C_s -symmetric N,N,N-Phosphorus Molecule

Although the T-shape phosphine described in the previous chapter displays fascinating N-H oxidative addition reactivity through a non-canonical electrophilic mechanism, extending this reactivity to further synthetic applications is limited by the lack of reversible bond activation reactivity.² This lack of reversibility can be rationalized by the proposed mechanism that requires exogenous amines for proton shuttling. To overcome the challenge associated with reversible bond addition/elimination, a novel phosphine compound designed to operate bond activation via an alternative mechanism is required.

The intermolecular N-H oxidative addition reactivity of the T-shape phosphine compound **3.1** results from its unique structure (**Figure 3.1**). In addition to causing lowering of the LUMO energy level and significant perturbation in electronic structure, the planar structure can be viewed as a trigonal bipyramidal geometry with two equatorial vacant sites available for additional bonding. The *cis*-divacant trigonal bipyramidal structure minimizes the energetic penalty associated with the geometric reorganization

during the transformation from phosphine to trigonal bipyramidal σ^5 -phosphorus molecules. For the similar reason, we imagined that if the planar geometry of a phosphine **3.1** were further modified and become closer to trigonal pyramidal geometry, the energy barrier of P(V) reductive elimination and P(III) formation may be reduced (**Figure 3.1**). Also, replacing the ligand oxygens of **3.1** with more basic nitrogen atoms might transform the E-H activation mechanism from the exogenous amine-assisted process to an intramolecular ligand-assisted pathway, in which the ligand nitrogens acting as the built-in proton shuttles and make the E-H elimination possible in the absence of exogenous amine.

Figure 3.1. Design of phosphine **3.2** with fine-tuned geometry that benefits P(III) regeneration.

With this concept in mind, our group has recently reported the preparation and reactivity of geometrically deformed phosphorous triamide **3.2** (**Figure 3.1**, *bottom*). X-ray crystallography reveals that solid state structure of **3.2** has a significant folding along the central P-N axis (**Figure 3.2**) and the N-P-N bond angles between proximal nitrogens are nearly right-angled and roughly equivalent ($\angle\text{N1-P-N2} = 90.51(6)^\circ$, $\angle\text{N1-P-N3} = 90.08(6)^\circ$). While the N-P-N angle between distal nitrogen atoms is much larger ($\angle\text{N2-P-N3} = 115.21(7)^\circ$), the distal P-N bonds are nearly same in length (P-N2 = 1.7014(1) Å, P-N3 = 1.7190(1) Å) and shorter than the central P-N bond (P-N1 = 1.7610(1) Å). To conclude, X-ray crystallography indicates that the P(III) triamide **3.2** adopts a C_s -symmetric geometry which efficiently retains the beneficial low σ^3 - σ^5 reorganization

Figure 3.2. Molecular structure of phosphine **3.2**. Thermal ellipsoid plot rendered at 50% probability level. Reproduced with permission from *J. Am. Chem. Soc.* **2014**, *136*, 17634.

Figure 3.3. The reactivity of phosphine **3.2**. (Top) Phosphorus–ligand cooperative addition of protic E–H substrates to **1**. (Bottom) Regioisomeric phosphorus–ligand cooperative addition of hydridic E–H to **3.2**.

barrier as phosphine **3.1** while having a less severe distortion from P(III) C_{3v} geometry.

Phosphine **3.2** was found to undergo rapid edge inversion through a C_2 symmetric planar transition state and an unusually low barrier, suggesting conformational flexibility between its bent ground state and a metastable planar geometry. In common with the previously studied planar O,N,O-chelated phosphine **3.1**, C_s -symmetric **3.2** also exhibits an anomalously low nucleophilic reactivity. Different from traditional phosphines, compound **3.2** demonstrates biphilic reactivity and reacts with E–H bonds (E = -OR, -NHR) on the phosphorus center with a reversible oxidative addition–reductive

elimination process. Mechanistically, we have shown that the formal oxidative addition process operates in a stepwise phosphorus–ligand cooperative mechanism (**Figure 3.3 top**), wherein the protic E–H substrate reacts initially with one of the **3.2** axial P–N linkages to give a σ^3 -phosphorus intermediate **3.3**, in which a new P–E bond is formed and the resultant proton is accommodated on a methylanilide nitrogen. Subsequent intramolecular $\sigma^3 \rightarrow \sigma^5$ ring–chain tautomerism then affords the overall oxidative addition product **3.4**.

Inspired by the previous studies, we envisioned the alternative reactivity from the same phosphorus–ligand cooperative activation but with formally hydridic E–H substrates such as boranes (**Figure 3.3 bottom**). Inverted regioselectivity for the E–H addition to **3.2** could be expected due to the opposite substrate polarization, leading to the hydride-phosphorus interaction and the migration of attendant E^+ fragment to the ligand methylanilide nitrogen. This alternative mode of activation would result in the formation of a P-hydrido-1,3,2-diazaphospholene **3.5**, a class of compounds that Gudat³ has reported to exhibit significant hydridic reactivity due to the strong electronic interaction between P–H σ^* orbital and the neighboring phosphacyclic nitrogen lone pairs. We aimed to investigate this phosphorus–ligand cooperative E–H activation reactivity and explore the potential catalytic E–H transfer results from the combination of the reactivity of intermediate **3.5** and subsequent E^+ group transfer from the pendant N-methylanilide.

In the following sections, we present the phosphorus–ligand cooperative reactivity for borane B–H addition to C_s -symmetric phosphine **3.2**. We also demonstrate

that the B-H activation can be further utilized to catalytic imine hydroboration. Through spectroscopic and kinetic analyses, the phosphorus–ligand cooperativity and the reversible addition and elimination across a reactive P–N linkage are confirmed. The study expands the scope of ligand cooperative catalytic reactivity in the main group chemistry and promises a broader opportunity for future design of phosphorus-based bifunctional and ligand cooperative catalysts.

3.2 Stoichiometric Phosphorus-Ligand Cooperative B-H Activation

Bifunctional reactivity resulting from the cooperative action of donor and acceptor functionalities placed within close structural proximity is a potent strategy for the modification of chemical bonds. The significance of cooperative bond activation is well exemplified in the literature of transition metal catalysis,⁴ where activation of a substrate's covalent bond arises from the mutual participation and modification of both a reactive metal center and supporting ligand. Reported ligand-cooperative reactivities across diverse transition metals and ligand structures indicate its generality.⁵

Although attracting less attention, ligand cooperativity are also evident in the chemistry of the main group; recent stoichiometric examples from Groups 2,⁶ 13,^{7,8} 14,^{9,10} and 15¹¹ are representative. These studies regarding main group element–ligand cooperativity contribute to current interest into the qualitative connections between the chemistry of transition metals and the main group.¹² In a compelling application of such stoichiometric reactivity to catalysis, Berben has demonstrated the cooperative

metal–ligand reactivity of aluminum-bis(imino)pyridine compounds in catalytic amine¹³ and formic acid¹⁴ dehydrogenation.

In transition metal chemistry, borane B–H activation via oxidative addition¹⁵ and metal-ligand cooperativity¹⁶ is well-studied and many catalytic hydroboration applications are based on these fundamental bond activation reactions.¹⁷ Main group B–H activation such as 1,1-oxidative addition by carbenes¹⁸ is also precedented. However, formally heterolytic reactivity modes are more common, for instance FLP-type activation¹⁹ in the presence of Lewis bases or formally metathetical transformations across polarized σ -bonds²⁰ are found in catalytic applications.²¹ In addition, although not rigorously involving B–H activation, the Corey-Bakshi-Shibata method is also an excellent example of bifunctional main group catalyzed hydroboration.²²

To test our hypothesis that **3.2** would exhibit a bifunctional, phosphorus-ligand cooperative reactivity toward B–H bonds, a solution of **3.2** (0.13 M in C₆D₆) was treated with one equiv. of pinacolborane (HBpin) (**Figure 3.4**). Over the course of 12 h at 50 °C, ³¹P NMR spectra indicated the complete consumption of **3.2** (δ 159.9 ppm) and formation of a major new phosphorus species **3.6** with a chemical shift δ 84.2 ppm (d, J = 146 Hz). Both the ³¹P chemical shift and multiplicity are indicative of a tricoordinate phosphorus species with a direct P–H linkage. The presence of a P–H moiety is further supported by ¹H NMR spectra of compound **3.6**, which display a new doublet signal centered at δ 6.88 ppm with a complementary coupling (J = 146 Hz) to that observed in ³¹P NMR spectra. Additionally, the ¹H NMR spectra show that compound **3.6** adopts a less symmetric

molecular geometry than phosphine **3.2**; the originally homotopic *N*-methyl groups from **3.2** transform into two distinct signals (δ 3.05, 2.55 ppm) in **3.6**. Only one of the *N*-methyl signals (δ 2.55 ppm) displays $^3J_{\text{P-H}}$ coupling ($J = 15$ Hz), suggesting the release of one *N*-methylanilide substituent from the phosphorus center of **3.2** upon reaction with HBpin. A ^{11}B NMR resonance at 24.2 ppm also confirms the existence of the boron nucleus in the structure of **3.6**.

Figure 3.4. Activation of pinacolborane with **3.2** and resulting *P*-hydrido-1,3,2-diazaphospholene **3.6**.

3.3 Characterization of the *P*-Hydrido-Diazaphospholene Intermediate

Figure 3.5. Annotated partial two-dimensional 1H - 1H NOESY spectrum of **3.6** showing correlations between protons that share dipolar coupling (C_6D_6 , 298 K, 500 MHz). Reproduced with permission from *J. Am. Chem. Soc.* **2017**, *139*, 6008.

Further information regarding the structure of **3.6** is obtained from two-dimensional NOESY spectra (**Figure 3.5**). Cross peaks indicate ^1H - ^1H NOE correlation signals between H^1 (i.e. P-H) and both H^6 and H^7 (*N*-methyl C-Hs), confirming the ring-opened structure of the ligand framework. Also, the correlation between H^8 (pinacol methyl C-Hs) with both H^1 and H^7 confirm the presence of the Bpin moiety on the pendant *N*-methylanilide arm. Taken together, these spectral data are consistent with the identity of **3.6** as a *P*-hydrido-1,3,2-diazaphospholene arising from P-N cooperative activation of the B-H bond of HBpin. Potential atropisomeric diastereomers, which were previously observed in the analogous O-H activation intermediate **3.3**, are not resolved spectroscopically for **3.6** presumably due to the small size of the P-H moiety. Compound **3.6** is stable (0.12 M, 95 % NMR yield) in d_6 -benzene solution but undergoes decomposition to a σ^5 -P dihydridophosphorane upon prolonged standing in the presence of excess HBpin.

3.4 Hydridic Reactivity of the P-hydrido-diazaphospholene 3.6 toward Alkyl Halides and Imines

Inspired by the studies in the effects of endocyclic hyperconjugation on the reactivity of 1,3,2-diazaphospholenes,²³ the hydridic behavior of **3.6** was evaluated. Indeed, low NMR $^1J_{\text{P-H}}$ value (146 Hz) indicates a weak P-H bond and NBO charge analysis implicates a hydridic nature of the P-H moiety in **3.6** (atomic charge of -0.11). In agreement with these analyses, the addition of chloroform to a solution of **3.6** (78 mM

in C_6D_6) resulted in conversion over the course of 6 h to a new phosphorus species (^{31}P NMR δ 146.4 ppm) consistent with the assignment as *P*-chloro-1,3,2-diazaphospholene **3.7** (Figure 3.6). Compound **3.7** may also be obtained directly from treatment of **3.2** with HBpin in dichloromethane or chloroform solution for further identification of compound **3.7**. Surprisingly in this latter reaction, accumulation of *P*-hydrido-diazaphospholene intermediate **3.6** is not observed in the solution. This observation indicates that the reaction consuming intermediate **3.6** (with the halogenated substrate) happens more rapidly than the reaction generating **3.6** (from **3.2** by HBpin activation), consistent with the potent hydricity of *P*-hydrido-1,3,2-diazaphospholene **3.6**.

Figure 3.6. Hydrodechlorination of chloroform by **3.6** and formation of **3.7**.

Crystalline samples of **3.7** for x-ray crystallography were prepared by crystallization from CH₂Cl₂/pentane solution. The molecular structure (**Figure 3.7**)²⁴ unambiguously confirms the tricoordinate phosphorus local environment with pendant N(Bpin) moiety, supporting the analogous structural assignment for P-hydrido-diazaphospholene **3.6**. P-Cl compound **3.7** displays a small displacement (0.251 Å) of phosphorus from the C₂N₂ plane and a rather long P–Cl bond length (2.276(1) Å, compare 2.180(4) Å for (Me₂N)₂PCl²⁵), indicative of hyperconjugative n(π)→σ* overlap as has been reported in related compounds by Gudat. It is reasonable to assume that P-H compound **3.6** experiences similar electronic interactions that underpin its hydridic reactivity.

Figure 3.7. Molecular structure of **3.7** with 50% probability level rendered thermal ellipsoid plot. Reproduced with permission from *J. Am. Chem. Soc.* **2017**, *139*, 6008.

To further evaluate its hydricity with respect to organic substrates, treatment of P-H diazaphospholene **3.6** with *N*-tosylbenzaldimine at ambient temperature in benzene

(**Figure 3.8 top**) resulted in complete conversion to a phosphorus species **3.8** with a ^{31}P NMR signal at δ 92.6 ppm. X-ray crystallography confirms the addition of **3.6** into the imine through a formal hydrophosphination and the formation of a phosphorus triamide with the Bpin moiety on a pendant *N*-methylanilide arm (**Figure 3.9**). As in the case of alkyl chloride reduction, compound **3.8** may also be accessed directly from C_s -symmetric phosphine **3.2** by treatment with *N*-tosylbenzalimine and HBpin at ambient temperature (**Figure 3.8 bottom**). The P-H diazaphospholene **3.6** is a presumed but unobservable intermediate in this preparation. Compound **3.8** is a stable species in both the solid state and solution; no decomposition is observed after heating a C_6D_6 solution at 60 °C for 48 h.

Figure 3.8. Reduction of *N*-tosylbenzalimine and the formation of the triazaphospholene **3.8**.

Figure 3.9. Molecular structure of **3.8** with 50% probability level rendered thermal ellipsoid plot. Reproduced with permission from *J. Am. Chem. Soc.* **2017**, *139*, 6008.

3.5 Cooperative B-N Elimination of the Triazaphospholene Intermediate

In contrast to the simple hydrophosphination of *N*-tosylbenzaldimine and the generation of stable triazaphospholene compound **3.8**, reaction of **3.6** with an *N*-alkyl benzaldimine results in a remarkably different outcome. Treatment of a C_6D_6 solution of **3.6** with *N*-benzyl *p*-methoxybenzaldimine (**3.9**) at ambient temperature resulted in the consumption of **3.6** and the unexpected generation of C_s -symmetric phosphine **3.2** (**Figure 3.10**). 1H NMR spectra also confirm the concomitant formation of hydroboration product **3.11** under these conditions.

Figure 3.10. Reduction of imine **3.9** with P-H diazaphospholene **3.6** and the regeneration of **3.2**.

In situ ^{31}P NMR monitoring during the reaction provides additional insight of this transformation (**Figure 3.11**). In situ generated **3.6** in C_6D_6 , was treated with imine **3.9**. As the reaction progresses (**Figure 3.11b** and **c**), the concentration of **2** decreased while the concentration of **3.6** was simultaneously observed to increase. Also observed in these spectra is the appearance of a transient minor peak δ 105.1 ppm. Based on the ^{31}P NMR chemical shift of this signal, we considered that this species might correspond to the phosphorous triamide **3.10** from hydrophosphination of imine **3.9** with P-H diazaphospholene **3.6**. Indeed, independent synthesis of **3.10** from treatment of P-Cl compound **3.7** with *N*-benzyl-*N*-(*p*-methoxyphenyl)methanamine (**Figure 3.12**) gives the same ^{31}P NMR signal δ 105.1 ppm. Consistent with the above observations, intermediate **3.10** is metastable in solution but not isolable. Instead, independently synthesized **3.10** decomposes cleanly to C_s -symmetric phosphine **3.2** within 60 h at ambient temperature (^{31}P NMR spectra, **Figure 3.13**). Correspondingly, 1H NMR spectra confirm the formation of the *N*-borylamine product **3.11** by B–N elimination from **3.10**.

Figure 3.11. Representative time-stacked ^{31}P NMR spectra (C_6D_6 , 145.79 MHz, 25 °C) for the reaction of **3.6** (δ 84.2 ppm) with imine **3.9** to give **3.2** (δ 159.9 ppm) via **3.10** (δ 105.1 ppm) at time points: (A) 10 min, (B) 30 min, (C) 12 h. Asterisk marks unidentified byproduct (δ 140 ppm).

Figure 3.12. The independent synthesis of **3.10** and its elimination of the *N*-borylamine **3.11**. PMP=*p*-methoxyphenyl.

Figure 3.13. Time-stacked ^{31}P NMR spectra (C_6D_6 , 145.79 MHz, 25 °C) for the conversion of **3.10** to **3.2** at time points (A) 10 min, (B) 3 h, (C) 12 h, (D) 36 h, (E) 60 h. Reproduced with permission from *J. Am. Chem. Soc.* **2017**, *139*, 6008.

Since compound **3.10** is not isolable, an analogous phosphorous triamide **3.12** (δ 91.3 ppm) was prepared by treatment of **3.7** with benzylamine for further structure confirmation (**Figure 3.14**). The composition of this compound was unambiguously proven by X-ray diffraction analysis of single crystalline samples (**Figure 3.15**). The similarity in ^{31}P NMR chemical shifts between isolable **3.12** and transient **3.10** supports the assignment of **3.10** as the phosphorous triamide depicted in **Figure 3.10**. In a further analogy to **3.10**, compound **3.12** can be directly converted to **3.2** upon heating (50 °C, 48 h) with liberation of *N*-boryl benzylamine **3.13**. Taken together, the experiments present

above demonstrates that the *N*-boryl benzylamines are generated from the phosphorous triamide intermediates via a ligand-phosphorus cooperative pathway.

Figure 3.16. Kinetics experiments of the cooperative HBpin activation with **3.2**. (A) Plot of **[3.2]** vs time monitored ($[\mathbf{3.2}]_0 = 78$ mM, $[\mathbf{HBpin}]_0 = 117$ mM, C_6D_6 , 297 K). (Inset) Plot of $\ln[\mathbf{3.2}]$ vs time with linear least-squares fit. (B) Plot of k_{obs} vs $[\mathbf{HBpin}]_0$ with linear least-squares fit. Reproduced with permission from *J. Am. Chem. Soc.* **2017**, *139*, 6008.

3.6 Kinetic Analysis of the Cooperative B–H Activation

Kinetic analyses were conducted to elucidate the reaction rate and molecularity of the phosphorus-ligand cooperative B-H activation. Using 1,3,5-trimethoxybenzene as the internal standard, the reaction of **3.2** (78 mM in C₆D₆) with excess HBpin (15 equiv.) was monitored via ¹H NMR as a function of time and the result reveals a pseudo-first order dependence on **3.2** (**Figure 3.16A**). Plots of k_{obs} vs. [HBpin]₀ (**Figure 3.16B**) demonstrate a linear relationship over the concentration range 0.78 M ≤ [HBpin] ≤ 2.73 M, thus establishing an overall second order reaction rate law for addition of HBpin to **3.2** (eq **3.1**, $k = 4.76 \times 10^{-5} \text{ M}^{-1}\text{s}^{-1}$ at 25 °C) which is consistent with the direct bimolecular phosphorus-ligand cooperative activation of the B–H bond.

3.7 Kinetic Analysis of the Cooperative B–N Elimination

The kinetic analysis was also conducted by NMR monitoring of the conversion from **3.10** to **3.2**. Compound **3.10** was in situ prepared in solution and purification by rapid filtration over celite to eliminate triethylammonium chloride. The decay of **3.10** was then monitored at ambient temperature by ¹H NMR spectroscopy to greater than 75% conversion (**Figure 3.17**). The linear relationship between ln[**3.10**] and time (**Figure 3.17 inset**) demonstrates a first-order reaction kinetics as expected for a unimolecular

decomposition of **3.10**. The extracted rate constant ($k = 0.04 \text{ s}^{-1}$) is independent of absolute concentration within the range $0.58 \text{ mM} < [\mathbf{3.10}] < 3.26 \text{ mM}$. These results are fully consistent with a ligand cooperative intramolecular transfer of the boryl unit from the *N*-methylanilide arm to the *N*-benzyl-*N*-(*p*-methoxyphenyl)methanamine fragment, elimination of *N*-borylamine **3.11**, and reconstitution of a P–N bond in the conversion of **3.10** to C_s -symmetric phosphine **3.2**.

Figure 3.17. Kinetics experiments of the cooperative B–N elimination from **3.10**. Plot of **[3.10]** vs time monitored ($[\mathbf{3.10}]_0 = 3.3 \text{ mM}$, C_6D_6 , 297 K). (*Inset*) Plot of $\ln [\mathbf{3.10}]$ vs time with linear least-squares fit. Reproduced with permission from *J. Am. Chem. Soc.* **2017**, *139*, 6008.

3.8 Catalytic Reactivity toward Imine Hydroboration

With the stoichiometric reactivities in mind, we pursued investigations of hydroboration reactions catalyzed by C_3 -symmetric phosphine **3.2**. In an initial attempt, a C_6D_6 solution of *N*-benzyl *p*-anisaldimine **3.9** (1 equiv.) and HBPin (1 equiv.) was exposed to 10 mol% of **3.2** at 50 °C. After 24 hours, imine **3.9** was completely converted to the hydroboration product **3.11** (**Figure 3.18 top**). Control reactions between **3.9** and HBPin under identical reaction conditions without catalytic **3.2** show less than 15% conversion (**Figure 3.18 bottom**), consistent with a transformation that is indeed under catalyst control.

Figure 3.18. Catalytic imine hydroboration reactivity of **3.2**.

In situ NMR monitoring of the catalytic transformation was conducted to further substantiate the action of **1** during catalysis. After mixing of imine **3.9**, HBPin, and 10

Figure 3.19. Catalytic imine hydroboration reactivity of **3.2**.

mol% **3.2** in C₆D₆ at 50 °C in a thermostatted probe, a ³¹P NMR spectrum indicates the formation of small quantities of P-H diazaphospholene **3.6** at the expense of the initial concentration of **3.2**. At subsequent intermediate time points (time = 0.5-12 h), the concentrations of **3.6** showed no significant change. As the reaction progressed over the next 24 h, continued production of the corresponding hydroboration product **3.11** could be observed by ¹H NMR spectra. Catalyst **3.2**, although diminished, was never completely consumed. The existence of **3.2** during the entire course of catalytic reaction as opposed to its total conversion to **3.6** in stoichiometric reaction suggested again that the reduction of the imine by **3.2** leads to an ephemeral intermediate **3.10** which

decomposes to give **3.2** and the hydroboration amine product. The mechanism of phosphine **3.2**-catalyzed imine hydroboration is illustrated in **Figure 3.19**.

Under the same catalytic conditions, imines with varied substituents are reduced catalytically and produce the corresponding hydroboration products (**Figure 3.20**). Aldimines with *N*-aryl (**3.15**), *N*-alkyl (**3.16**), and electronically diverse (**3.18-3.23**) substitutions are tolerated. Ketimines are also reduced under the catalytic conditions (**3.26 – 3.28**) but with lower yields presumably caused by a steric effect.

Figure 3.20. Phosphine **3.2** catalyzed aldimine and ketamine hydroboration.

Our study of C_s -symmetric **3.2** and related distorted structures concerns the increased electrophilic character at phosphorus due to deformation from local threefold phosphorus center. Enthalpic (strain) arguments have been discussed in related systems that account for this observation²⁶ and this mode of reactivity is accentuated in the case of **3.2** due to the geometric constraint imposed by the triamide framework. In addition to our previous investigation of the increased electrophilicity at phosphorus of **3.2** and the resulting reactivity of **3.2** toward protic E–H substrates (E = OR, NHR), here we access a regioreversal by reaction with a hydridic E–H (E = Bpin) compound. In the transformation, the acceptance of a hydride at phosphorus occurs in a bimolecular pathway and accompanies with the boryl transfer to the pendant *N*-methylanilide with P–N cleavage. The regioselectivity of the B–H activation is unusual due to the ubiquity of phosphine-borane dative interactions, presumably both the weak *P*-nucleophilicity of **3.2** and weak *B*-electrophilicity of HBpin disfavor the common P→B Lewis acid-base interaction.

3.9 Conclusion and Outlook

C_s -symmetric σ^3 -phosphorous compound **3.2** has been demonstrated to be a capable catalyst for the hydroboration of imines, and the mechanistic details of this transformation have been elucidated. The reactivity arises from the cooperative action of an electrophilic P(III) center and a proximal basic *N*-methylanilide nitrogen within a distorted molecular environment imposed by the triamide ligand. The bimolecular,

phosphorus-ligand cooperative mechanism is involved in both the initial B–H activation and the B–N elimination. The regeneration of the deformed phosphabicyclic structure of **3.2** happens with the concomitant formation of the hydroboration products. The ability of distorted phosphorous triamide **3.2** to catalyze B–H transfer through a P-N ligand cooperative mechanism promises further opportunity for targeted design of novel main group catalysts. On the basis of the described experimental results concerning the impact of geometry distortion on the reactivity of σ^3 -phosphorus compounds, σ^4 -phosphorus molecules with analogously constrained frameworks were also investigated and their potentials in activations of a range of E–H will be discussed in the following chapter.

3.10 Experimental

General Materials and Methods

All reagents were purified as described in the previous chapter. Pinacolborane was purified by vacuum distillation (60 torrs) and stored in a nitrogen-filled glovebox. Benzylamine was purified by distillation from zinc dust and stored over 3 Å molecular sieves prior to use. All glassware was oven-dried at 120 °C prior to use. All reactions were carried under dry nitrogen atmosphere (Schlenk line or glovebox) unless otherwise noted. NMR spectra were recorded on a Bruker AV-360 (360MHz), a Bruker AV-400 (400 MHz), a Bruker AV-500 (500MHz) or a VARIAN Inova-500 (500MHz) spectrometer. ^1H NMR chemical shifts are given in ppm with respect to solvent residual peak (C_6D_6 , δ 7.16 ppm; CDCl_3 , δ 7.26 ppm; CD_2Cl_2 , δ 5.32 ppm), $^{13}\text{C}\{^1\text{H}\}$ NMR shifts

are given in ppm with respect to CDCl_3 (δ 77.16 ppm), C_6D_6 (δ 128.06 ppm) or CD_2Cl_2 (δ 53.84 ppm). Coupling constants are reported as J -values in Hz. High resolution EI and ESI mass spectra were obtained from the Mass Spectrometry Laboratory at the School of Chemical Sciences, University of Illinois at Urbana-Champaign or Department of Chemistry Instrumentation Facility, Massachusetts Institute of Technology.

Synthetic Procedures and Characterization Data

Phosphorus compound **3.2** was prepared by minor modification of the literature¹ method according to the following sequence (**Figure 3.21**):

Figure 3.21. Synthesis of phosphine **3.2**.

S3.1

Bis(2-nitrophenyl)amine (S3.1): Synthesized according to literature procedure.¹ 1-Fluoro-nitrobenzene (20.0 mL, 190 mmol), 2-nitroaniline (26.2 g, 190 mmol) and K₂CO₃ (31.4 g, 228 mmol) were mixed in DMSO (300 mL). The reaction mixture was stirred at 120 °C for 36 h.

H₂O was then added (300 mL), and the mixture was extracted with dichloromethane (3 x 500 mL). The combined organic layer was washed with a saturated aqueous solution of NaCl (6 x 300 mL, 15 %), dried over anhydrous magnesium sulfate and concentrated *in vacuo*. The product was obtained as an orange solid (46.5 g, 95 %) and was used for next step without further purification. ¹H NMR (360 MHz, CDCl₃): δ 10.98 (s, 1H), 8.16 (dd, 2H, *J* = 8.4 Hz, *J* = 1.3 Hz), 7.58-7.48 (m, 4H), 7.09-7.04 (m, 2H) ppm.

S3.2

Bis(2-aminophenyl)amine (S3.2): Synthesized according to literature procedure.¹ Bis(2-nitrophenyl)amine **S3.1** (10 g, 38.5 mmol) was suspended in EtOAc (100 mL). Palladium on carbon (790 mg, 10 wt%) was then added to the solution. The reaction mixture was transferred to a

high pressure reactor, charged with hydrogen (400 psi), and stirred for 10 h. Upon completion, the solution was filtered through Celite and concentrated to a dark residue under vacuum, which was used in the next step without further purification (5.43 g, 94%). ¹H NMR (360 MHz, CDCl₃): δ 6.97-6.92 (m, 2H), 6.80-6.74 (m, 6H), 5.00 (br s, 1H), 3.74 (br s, 4H) ppm.

S3.3

Bis(2-methylaminophenyl)amine (S3.3): Synthesized via a modified literature procedure.¹ To a mixture of bis(2-aminophenyl)amine **S3.2** (10 g, 50.1 mmol) and paraformaldehyde (14.8 g, 494 mmol) in anhydrous methanol (500 mL) was added a solution of NaOMe in

methanol (34.5 mL, 25 wt. %) slowly at 0 °C. The mixture was then stirred under reflux for 1 h. After being cooled to 0 °C, NaBH₄ (20.6 g, 545 mmol) was added in small portions. The solution was again stirred with heating to reflux for 1 h. The reaction mixture was then cooled to room temperature. To this mixture, 1 M NaOH (150 mL) was

added followed by extraction dichloromethane (3 × 300 mL). The combined organic phase was filtered after dried over magnesium sulfate. The crude mixture was concentrated under vacuum and flushed through a short column of silica gel with dichloromethane. After concentration, the resulting crude solid was recrystallized from ethanol to give the product as purple crystals (9.8 g, 87 %). ¹H NMR (360 MHz, CDCl₃): δ 7.07 (m, 2H), 6.77-6.71 (m, 6H), 4.91 (s, 1H), 3.76 (br s, 2H), 2.88 (s, 6H) ppm.

Compound 3.2. Synthesized via a modified literature procedure.¹ Phosphorus trichloride (1.15 mL, 13.2 mmol) was dissolved in ether (40 mL) and cooled to -78 °C. A solution of triamine **S3.3** (3.00 g, 13.2 mmol) in THF (10 mL) was added dropwise via syringe. Upon completion, an ether solution (36 mL) of triethylamine (5.60 mL, 40.2

mmol) was added slowly via syringe. The reaction mixture was stirred at -78 °C for 1h and then warmed to room temperature. After 4h of stirring at room temperature, all volatiles were solvent was removed *in vacuo* and the resulting solid mixture was moved into a nitrogen-filled glovebox. The solid mixture was stirred in pentane and filtered through Celite to remove all insoluble solids. Pentane was removed *in vacuo* and the resulting crude product was recrystallized with pentane in a freezer (ca. -35 °C) to yield **3.2** as light-pink crystals (2.5 g, 75 %). ¹H NMR (C₆D₆, 400 MHz): δ 7.38 (dd, 1H, *J* = 7.7, 1.3 Hz), 6.94 (td, 1H, *J* = 7.6, 1.2 Hz), 6.77 (td, 1H, *J* = 7.6, 1.3 Hz), 6.34 – 6.29 (m, 1H), 2.52 (d, 3H, *J* = 8.3 Hz). ³¹P NMR (C₆D₆, 162 MHz): δ 159.8 ppm.

Compound 3.6. Under nitrogen atmosphere, pinacolborane (15 mg, 0.12 mmol) was mixed with a C₆D₆ solution (1 mL) of compound **3.2** (30 mg, 0.12 mmol) in a sealable threaded NMR tube. The mixture was kept at

50 °C for 12 h to afford crude **3.6** (NMR yield: 95 %). ¹H NMR (C₆D₆, 500 MHz): δ 7.29

(d, 1H, $J = 7.8$ Hz), 7.20 (d, 1H, $J = 7.8$ Hz), 7.07 (d, 1H, $J = 7.7$ Hz), 6.92-6.77 (m, 4H), 6.86 (d, 1H, $^1 J_{\text{P-H}} = 146.3$ Hz), 6.52 (d, 1H, $J = 7.8$ Hz), 3.05 (s, 3H), 2.85 (d, 3H, $J = 12.8$ Hz), 1.05 (s, 12H) ppm. ^{31}P NMR (C_6D_6 , 202 MHz): δ 84.2 (d, $J = 146$ Hz) ppm. MS (ESI) calcd for $\text{C}_{20}\text{H}_{27}\text{BN}_3\text{O}_2\text{P}$ (M) 383.1934 submitted.

Compound 3.7. Under nitrogen atmosphere, pinacolborane (50 mg, 0.39 mmol) was added into a CHCl_3 solution (2 mL) of compound 1 (100 mg, 0.39 mmol) and the solution was stirred under room temperature. After

12 h, all volatiles were re-moved *in vacuo* and the remaining white solid was recrystallized in pentane to afford **3** as a white crystals (80 mg, 70 %). ^1H NMR (CDCl_3 , 400 MHz): δ 7.64 (d, 1H, $J = 8.0$ Hz), 7.37-7.26 (m, 3H), 7.08 (t, 1H, $J = 8.0$ Hz), 7.01-6.97 (m, 2H), 3.39 (d, 3H, $J = 16.0$ Hz), 2.85 (s, 3H), 0.94 (broad s, 12H) ppm. ^{13}C NMR (CDCl_3 , 100 MHz): δ 145.0 (d, $^2 J_{\text{PC}} = 4.0$ Hz), 136.9 (d, $^2 J_{\text{PC}} = 12.0$ Hz), 132.02 (d, $^2 J_{\text{PC}} = 11.0$ Hz), 129.51, 129.45, 128.81, 128.31, 125.71, 121.52, 121.05, 111.94, 110.00, 82.74, 37.20, 29.44 (d, $^2 J_{\text{PC}} = 18.0$ Hz), 24.15 ppm. ^{31}P NMR (CDCl_3 , 145 MHz): δ 146.38 ppm. MS (ESI) calcd for $\text{C}_{20}\text{H}_{26}\text{BN}_3\text{O}_2\text{P}$ ($\text{M}^+ - \text{Cl}$) 382.1856 found 382.1859.

Compound 3.8. Under nitrogen atmosphere, a C_6D_6 solution of in situ generated **2** (1 ml, 0.24 M) was added *N*-tosyl-*I*-phenylmethanimine (64 mg, 0.24 mmol). The mixture was stirred at room temperature for 16 h, all volatiles were re-moved *in vacuo* and the resulting white solid was washed with pentane (60 mg, 63%). The solid was then recrystallized in a 10:1 pentane/ CH_2Cl_2 solution to obtain the samples for X-ray

crystallography. ^1H NMR (C_6D_6 , 400 MHz): δ 7.80 (d, 2H, $J = 7.9$ Hz), 7.53-7.50 (m, 2H), 7.37 (d, 1H, $J = 8.0$ Hz), 7.20-7.07 (m, 5H), 6.93-6.69 (m, 5H), 6.65 (d, 1H, $J = 7.4$ Hz), 6.05 (d, 1H, $J = 7.5$ Hz), 4.51 (d, 1H, $J = 15.9$ Hz), 3.69 (d, 1H, $J = 15.9$ Hz), 2.93 (s, 3H), 2.38 (d, 3H, $J = 11.8$ Hz), 2.07 (s, 3H), 1.12 (s, 12H) ppm. ^{13}C NMR (126 MHz) δ 145.1, 141.6, 139.5, 137.9, 137.7, 137.7, 137.0 (d, $^2J_{\text{PC}} = 10.1$ Hz), 134.1 (d, $^2J_{\text{PC}} = 12.6$ Hz), 129.8, 129.3, 129.1, 128.1, 126.8, 126.8, 125.2, 124.2, 119.9, 118.5, 108.6, 107.8, 82.8, 47.9, 36.2, 36.2, 28.6, 28.4, 24.6, 24.4. ^{31}P NMR (C_6D_6 , 145 MHz): δ 92.6 ppm. MS (ESI) calcd for $\text{C}_{34}\text{H}_{41}\text{BN}_4\text{O}_4\text{PS}$ 643.2679 (M^+H) found 643.2685.

Compound 3.10. Under nitrogen atmosphere, a 1:1 THF/ether solution (2 ml) of **3** (10 mg, 2.39×10^{-2} mmol) and an ether solution (1 ml) of *N*-benzyl-1-(4-methoxyphenyl)methanamine (12 mg, 4.79×10^{-2} mmol) were both cooled to -30 °C and then

mixed together. The resulting cloudy mixture was quickly filtered through Celite and all volatiles were removed in vacuo to afford crude **6**. (NMR yield 82 %). ^1H NMR (C_6D_6 , 500 MHz): δ 7.56 (d, 1H, $J = 11.0$ Hz), 7.40 (d, 1H, $J = 11.0$ Hz), 7.23-6.80 (m, 12H), 6.80 (d, 2H, $J = 11.5$ Hz), 6.67 (d, 1H, $J = 10.5$ Hz), 4.25 (broad s, 2H), 3.70 (broad s, 2H), 3.45 (s, 3H), 3.20 (s, 3H), 3.04 (d, 3H, $^3J_{\text{PH}} = 13.8$ Hz), 1.16 (broad s, 12H) ppm. ^{31}P NMR (C_6D_6 , 145 MHz): δ 105.2 ppm.

Compound 3.12. Under nitrogen atmosphere, benzylamine (26 mg, 0.24 mmol) was added into a CH_2Cl_2 solution of **3** (50 mg, 120 mM). The

resulting cloudy solution was quickly filtered through Celite and all volatiles were removed *in vacuo* to afford crude product. The crude product was recrystallized in a 1:5 dichloromethane:pentane solution to afford **8** as a white crystals. ^1H NMR (CD_2Cl_2 , 360 MHz): δ 7.40-7.21 (m, 3H), 7.08 (d, 1H, $J = 7.0$ Hz), 6.83 (t, 1H, $J = 7.3$ Hz), 6.68 (t, 1H, $J = 7.6$ Hz), 6.61 (d, 1H, $J = 7.5$ Hz), 6.56 (d, 1H, $J = 7.5$ Hz), 3.72-2.64 (m, 2H), 3.07 (d, 3H, $J = 10.3$ Hz), 2.75 (s, 3H) ppm, 1.17 (s, 12H). ^{31}P NMR (CD_2Cl_2 , 145 MHz): δ 91.34 ppm. ^{13}C NMR (CD_2Cl_2 , 125 MHz): δ 144.48, 143.94, 140.89, 129.25, 128.96, 128.34 (d, $^2J_{\text{PC}} = 11.3$ Hz), 127.41, 127.03, 126.76, 126.54, 126.18, 125.15, 118.74, 117.31, 105.99, 82.63, 46.41, 44.84, 35.86, 29.02 (d, $^2J_{\text{PC}} = 21.2$ Hz), 24.33 ppm. MS (ESI) $\text{C}_{27}\text{H}_{35}\text{BN}_4\text{O}_2\text{P}$ ($\text{M}^+\text{+H}$) calc'd: 489.2591; found: 489.2595.

Pseudo-first Order Kinetic Study of the B-H Activation Reaction

Figure 3.22. Kinetic Study of the B-H Activation Reaction of **3.2**.

Experiments were conducted with varying equivalent of HBPin with at least 10-fold excess. Measurements were performed on a Bruker AV-400 NMR spectrometer. A stock solution of compound **3.2** (0.6 ml, 13 mM in C_6D_6 containing 0.06 mmol 1,3,5-trimethoxybenzene as the internal standard) and HBpin were added to a volumetric flask

and the resulting mixture was diluted to 1 ml with C_6D_6 . The diluted solution was then transferred to a J-Young NMR tube and the conversion of **3.2** to **3.6** was monitored with 1H NMR at ambient temperature. The concentrations of **3.2** were obtained from the NMR signal integral ratios between **3.2** and the internal standard. The error bars on the plot are generated from variability of 1H NMR integrals.

Kinetic Study of the B-N Elimination Reaction

Figure 3.23. Kinetic Study of the B-N Elimination Reaction of **3.10**.

In a nitrogen-filled glovebox, a 1:1 THF/ether solution (2 ml) of **3.7** (10 mg, 2.39×10^{-2} mmol) and an ether solution (1 ml) of *N*-benzyl-1-(4-methoxyphenyl)ethan-1-amine (12 mg, 4.79×10^{-2} mmol) were both cooled to $-30^\circ C$ and then mixed together. The resulting cloudy mixture was quickly filtered through Celite and all volatiles were removed in vacuo to afford crude **3.10**. (NMR yield 82 %). The

crude product was dissolved in 1 mL of C₆D₆ containing 1,3,5-trimethoxybenzene (2 mg, 1.9 x 10⁻² mmol) and the conversion of **3.10** to **3.2** and the *N*-borylamine **3.11** was monitored by ¹H NMR spectroscopy, with the varying concentrations of **3.10** and **3.2** determined at regular time intervals by ¹H NMR integration relative to internal standard. The error bars on the plot are generated from variability of ¹H NMR integrals.

Constrained Iminophosphoranes**

Chapter Four

Bond Activation Reactivity of Geometrically Constrained

Iminophosphoranes

The studies of the noncanonical reactivity of the C_{2v} and C_s -symmetric phosphines presented in the previous chapters provide strong supports to our hypothesis that reactivity of σ^3 -phosphorus molecules can be significantly altered by structural deformation. Bond activation reactivities arise from initial electrophilic interaction of phosphorus center and subsequent ligand-assisted or exogenous base-assisted transformation are realized as the geometry of phosphines distort away from a traditional pyramidal structure. In addition to providing valuable information about the impact of geometric distortion on the reactivity of σ^3 -phosphorus molecules, the investigations also inspired us to leverage geometry manipulation beyond σ^3 -phosphorus compounds by pursuing unprecedented reactivity in σ^4 -phosphorus species. We present in this chapter the preparation and chemical properties of iminophosphorane compounds with constrained O,N,O- and N,N,N-frameworks. Additionally, reactivity studies of the geometrically deformed iminophosphoranes toward B-H, B-O and Si-H bonds are discussed in this chapter.

4.1 Synthesis and Characterization of the Iminophosphoranes with Constrained O,N,O Ligand Framework

As discussed in Chapter 1, iminophosphoranes are σ^4 -phosphorus molecules with formally double-bonded nitrogen at the phosphorus atom that traditionally adopt pseudo-tetrahedral geometry. Although useful in the synthesis of amines,¹ amides² and heterocyclic compounds,³ the phosphorus center of iminophosphoranes is relatively unreactive due to the congested tetracoordinate environment and the energetically inaccessible phosphorus-localized frontier orbitals. Instead, the synergistic effect of low Lewis acidic phosphorus center and basic nitrogen in the structure of iminophosphorane makes the compound particularly useful in the chemistry of organic superbase and Lewis-base-catalyzed transformations.⁴

As can be rationalized by qualitative molecular orbital analysis, the electronic structure of tetracoordinate phosphorus molecules such as iminophosphoranes undergoes significant change upon geometry distortion (see **Figure 1.3**).⁵ Most dramatically, the LUMO is lowered by molecular distortion of iminophosphorane from tetrahedral to C_{2v} geometry. Coupled with the increased steric accessibility of the phosphorus center in this lower symmetric state, new possibilities in iminophosphorane chemistry might be expected if such compounds are accessible. In light of the unique structures and the resulting reactivity of C_{2v} ⁶ and C_s ⁷-symmetric phosphines, we were interested in the preparation of iminophosphoranes in the similar distorted O,N,O- and N,N,N-phosphabicyclic platforms (**Figure 4.1**).

Figure 4.1. Geometry distortion and new reactivity of σ^3 - and σ^4 -phosphorus molecules.

Iminophosphorane **4.2** with constrained O,N,O–ligand was prepared from the C_{2v} -symmetric phosphine **4.1** with the Staudinger method⁸ (**Figure 4.2**). Treatment of **4.1** with 1 equiv. of 2,6-diisopropylphenyl azide in C_6D_6 at 40 °C for 16 h resulted in a crude product mixture which showed a major ^{31}P NMR signal at 7.21 ppm. The chemical shift of the NMR resonance is consistent with compositionally related O,N,O–substituted iminophosphoranes in the literature.⁹ All volatiles were removed *in vacuo* and the resulting residue was triturated with pentane. The crude product thus obtained after filtration was purified to a white solid by recrystallization from a 10:1 dichloromethane/pentane solution. Crystalline samples of **4.2** suitable for X-ray diffraction were prepared by slow crystallization from CH_2Cl_2 /pentane solution. The molecular structure (**Figure 4.3**) confirmed that iminophosphorane **4.2** was obtained.

Figure 4.2. Synthesis of 4.2 from phosphine 4.1. dipp = 2,6-diisopropylphenyl.

It warrants noting that the transformation from phosphine 4.1 to 4.2 requires harsher reaction conditions and longer reaction times than typical for Staudinger procedures. This observation can be rationalized on a mechanistic basis. Staudinger reactions are proposed to proceed in stepwise fashion by the initial addition of phosphine to an azide substrate. In the case of 4.1, the initial nucleophilic interaction between the phosphine and azide is impeded due to the low nucleophilicity of the phosphorus center in 4.1.

4.2 Synthesis and Characterization of the Iminophosphoranes with Constrained N,N,N Ligand Framework

Iminophosphorane 4.4 with the N,N,N-ligand backbone was similarly prepared from C_s -symmetric 4.3 and 2,6-diisopropylphenyl azide (**Figure 4.4**). Treatment of 4.3 with 1 equiv. of 2,6-diisopropylphenyl azide in C_6D_6 at ambient temperature for 12 h resulted in a crude product with a major ^{31}P NMR signal at 14.5 ppm. Following solvent removal *in vacuo*, the resulting crude product was recrystallized from a 10:1 dichloromethane/pentane solution to afford the

crystalline samples of **4.4**. X-ray diffraction (**Figure 4.5**) confirmed that N,N,N-iminophosphorane **4.4** was obtained as a monomeric iminophosphorane.¹⁰

Figure 4.3. Molecular structure of **4.2** with 50% probability level rendered thermal ellipsoid plot. Selected bond lengths [Å] and angles [°]: P(1)–N(1) 1.690(1), P(1)–N(2) 1.507(1), P(1)–O(1) 1.604(1), P(1)–O(2) 1.596(1), C(1)–N(2) 1.399(2); O(2)–P(1)–N(2) 109.41(6), O(1)–P(1)–N(2) 115.31(6), N(1)–P(1)–N(2) 124.95(6), O(2)–P(1)–O(1) 112.61(5), O(2)–P(1)–N(1) 96.19(6), O(1)–P(1)–N(1) 96.68(5), P(1)–N(2)–C(1) 135.7(1).

Figure 4.4. Synthesis of **4.4** from phosphine **4.3**. dipp = 2,6-diisopropylphenyl.

Figure 4.5. Molecular structure of **4.4** with 50% probability level rendered thermal ellipsoid plot. 4.3 Structural Analysis of the Constrained Iminophosphoranes

In order to understand the structural deformation imposed by the O,N,O- and N,N,N-phoshabicyclic frameworks in compounds **4.2** and **4.4**, iminophosphoranes with undistorted O,N,O- and N,N,N-substituents and the same *N*-dipp substituent were synthesized for comparison from phosphines **4.5** and **4.6** (**Figure 4.6**).

Figure 4.6. Synthesis of acyclic iminophosphorane **4.5** and **4.6**. dipp = 2,6-diisopropylphenyl.

The solid samples of iminophosphoranes **4.5** and **4.6** are obtained from crystallization in CH_2Cl_2 /pentane solution and characterized by X-ray crystallography (**Figure 4.7** and **Figure 4.8**). To quantitatively evaluate the deviation of monomeric iminophosphorane **4.2** and **4.4** from tetrahedral geometry, geometry index parameter τ'_4 was calculated from the equation **4.1**:¹¹

$$\tau'_4 = \frac{\beta - \alpha}{360^\circ - \theta} + \frac{180^\circ - \beta}{180^\circ - \theta} \quad (4.1)$$

β and α are the two largest angles about the coordination center ($\beta > \alpha$) and $\theta = 109.5^\circ$. Under this definition, a tetrahedral structure would result in $\tau'_4 = 1$, whereas lower symmetry structures would have lower values (seesaw: $\tau'_4 = 0.36$; square planar: $\tau'_4 = 0$).

With the constrained O,N,O-phosphabicyclic framework, $\angle\text{O}(1)\text{-P}(1)\text{-N}(1)$ ($96.69(5)^\circ$) and $\angle\text{O}(2)\text{-P}(1)\text{-N}(1)$ ($96.19(6)^\circ$) of **4.2** are more contracted than the corresponding angles of acyclic **4.5** ($107.1(1)^\circ$ and $101.8(1)^\circ$) (**Table 4.1**). In addition, the angle between P=N and backbone P(1)-N(1) ($124.95(6)^\circ$) in **4.2** is significantly larger than **4.5** ($116.4(1)^\circ$), demonstrating a structure modestly distorted from conventional tetrahedral geometry toward the C_{2v} geometry with $\tau'_4 = 0.82$ (compare $\tau'_4 = 0.87$ for **4.5**). Similarly, O,N,O-phosphabicyclic iminophosphorane **4.4** has contracted endocyclic N(2)-P(1)-N(3) and N(3)-P(1)-N(4) angles ($92.35(5)^\circ$ and $92.84(5)^\circ$) and demonstrates an even more deviated structure with $\tau'_4 = 0.76$ (compare $\tau'_4 = 0.90$ for **4.6**) due to the larger angle ($129.23(6)^\circ$) between P=N and backbone P(1)-N(3) (**Table 4.2**).

Compared to acyclic iminophosphorane **4.5** ($d(\text{P}=\text{N})=1.484(2) \text{ \AA}$, $\angle(\text{P}=\text{N}-\text{C})=153.7(2)^\circ$), constrained O,N,O-iminophosphorane **4.2** has a longer P=N bond ($1.507(1) \text{ \AA}$) and a smaller P=N-C angle ($137.18(9)^\circ$) (**Table 4.1**), presumably indicating a weaker P=N π -interaction. By contrast, distorted N,N,N-

iminophosphorane **4.4** has similar P=N bond length (1.531(1) Å, **Table 4.2**) and P=N-C angle (129.23(6)°) with acyclic N,N,N-iminophosphorane **4.6** (P(1)-N(1) = 1.526(3) Å, \angle P(1)-N(1)-C(1) = 137.1(3)°) and suggesting a stronger P-N π -bonding interaction and less reactive phosphorus center than its constrained O,N,O-congener **4.2**.

4.4 Dimerization of the Geometrically Constrained Iminophosphoranes

Interestingly, O,N,O-iminophosphoranes with imino N-substituents less sterically encumbering than 2,6-diisopropylphenyl undergo rapid dimerization at ambient temperature and can only be isolated in a dimeric form. In fact, even the deformed O,N,O-iminophosphorane **4.2** with bulky 2,6-diisopropylphenyl (dipp) N-substituent undergoes gradual dimerization at ambient temperature. The formal [2+2]-dimerization of iminophosphorane P=N units is known in the literature, occurring predominantly for iminophosphoranes bearing strong electron-withdrawing substituents,¹² or otherwise atypical structures.^{13, 14} Consequently, the ready dimerization of O,N,O-iminophosphoranes **4.2** that lack strongly electron-withdrawing substituents is consistent with the hypothesis that a more Lewis acidic phosphorus center could be generated upon ligand distortion, facilitating the electrophilic interaction between the phosphorus centers and incoming electron donors such as the P=N nitrogen.

To differentiate the structural features between monomeric and dimeric iminophosphoranes in the constrained phosphorus ligation environment, the iminophosphoranes with N-substituted alkyl and aryl groups are prepared (**Figure 4.9 top**). In a typical cyclophosphazane preparation, treatment of **4.1** with 1 equiv. of the azide in C₆D₆ at 60 °C (note elevated temperature compared to preparation of monomeric compounds above) for 24 h gave only dimerized iminophosphoranes with ³¹P NMR signals in characteristic σ^5 -phosphorus region (**Figure 4.9 bottom**). The dimeric O,N,O-

iminophosphorane with N-2,6-diisopropylphenyl substituent could also be prepared from reacting **4.1** with the 2,6-diisopropylphenyl azide at 60 °C for 60 h. ^{31}P NMR signals of monomeric iminophosphoranes with N-dipp (**4.2**), N-tolyl (**4.7**), and N-mesityl (**4.8**) moieties can be detected as the reaction progresses. In contrast, iminophosphoranes with electron-withdrawing (**4.9** and **4.10**) and alkyl (**4.11** and **4.12**) N-substituents can only be observed in the dimeric forms. Single crystals of **4.2a**, **4.7a** and **4.8a** were obtained from benzene solutions and the X-ray diffraction patterns (**Figure 4.10**, **4.11** and **4.12**) confirmed a dimeric structure of the iminophosphoranes.

Figure 4.9. Synthesis of the dimerized *O,N,O*-iminophosphoranes.

Figure 4.10. Molecular structure of **4.2a** with 50% probability level rendered thermal ellipsoid plot.

Figure 4.11. Molecular structure of **4.7a** with 50% probability level rendered thermal ellipsoid plot.

Figure 4.12. Molecular structure of **4.8a** with 50% probability level rendered thermal ellipsoid plot.

The axial P-N bonds are observed to be longer than the equatorial P-N bonds in the structure of dimeric iminophosphorane **4.2a**, **4.7a** and **4.8a**, in line with expectations for structures of typical pentacoordinate trigonal bipyramidal molecules. The P=N bond of monomer **4.2** (1.507(1) Å) evolves on dimerization into the equatorial (1.664(2) Å) and axial (1.781(4) Å) P-N bonds in dimer **4.2a**, confirming the formation of covalently bonded four-membered cyclic structure in **4.2a** (as opposed to two closely packed monomers **4.2** in the solid state through the non-covalent interactions). Notably, the ^{31}P NMR resonance of dimer **4.2a** (-26.9 ppm) is significantly shifted down-field from the dimer **4.7a** (-45.7 ppm) and **4.8a** (-50.1 ppm). This ^{31}P NMR resonance shift to the less coordinate region can be explained by the existence of the bulkier N-dipp substituent and

the consequent larger separation between the two iminophosphorane sub-units in **4.2a**. The rationale is supported by the X-ray diffraction results, in which dimer **4.2a** displays longer bond length in both the axial P-N bond (1.781(4) Å) and the equatorial P-N bond (1.664(2) Å) than compound **4.7a** (axial P-N = 1.752(3) Å, equatorial P-N = 1.644(3) Å) and **4.8a** (axial P-N = 1.769(1) Å, equatorial P-N = 1.645(1) Å).

In accordance with larger separation between the two iminophosphorane sub-units in **4.2a**, dissolving the crystalline solid from the same sample used for X-ray diffraction of **4.2a** into C₆D₆ results in the regeneration of monomer **4.2** and a mixture with a 4:1 monomer/dimer ratio in ¹H and ³¹P NMR spectra. In addition, after removing C₆D₆ from this solution mixture and storing the resulting solid at room temperature for 10 days, the redissolved sample in C₆D₆ gives no change in monomer/dimer ratio. Dissolving the crystalline sample of less bulky *N*-substituted **4.7a** and **4.8a** gave only dimer NMR signals and no monomer/dimer interconversion. This observation suggests that the dimeric forms of the constrained iminophosphoranes are predominate in the solid state for less steric demanding substituents, but in the most sterically hindered case of **4.2** /**4.2a**, monomer and dimer forms are interconvertible in the solution phase and exist as mixtures.

Further modifications of the *N*-substituents in the structure of deformed O,*N*,O-iminophosphoranes provide more information associated with the P=N [2+2] dimerization. No monomeric species were observed during the preparation of the *N*-electron-withdrawing group-substituted compounds (**4.9a** and **4.10a** in **Figure 4.9**), suggesting that a more electron-deficient phosphorus center further enhances the [2+2]

dimerization process by providing stronger interaction with the P=N nitrogen of second monomer. In addition to the aryl azides, alkyl azides were also used in the preparations of N-alkyl-O,N,O-iminophosphoranes. In the reactions of **4.1** with primary and secondary azides (**4.11a** and **4.12a** in **Figure 4.9**), ^{31}P and ^1H NMR monitoring showed exclusively the signals from dimerized iminophosphoranes, indicating that a less sterically hindered environment on the imine nitrogen again facilitated the dimerization process.

Inspired by the observation that the electron-deficient metal center of zirconium imido complexes can be coordinated by electron-donating species such as THF,¹⁵ preparation of **4.2a** was attempted in d_8 -THF at 60 °C. In contrast to the reaction in C_6D_6 , *in situ* monitoring of the transformation with ^{31}P NMR in d_8 -THF showed that no dimerization happened during the process and the reaction eventually gave the pure monomeric product (^{31}P NMR δ 7.30 ppm in d_8 -THF). Presumably, THF prevents the dimerization of **4.2** by interfering with the intramolecular interaction between the Lewis acidic phosphorus center and the imino nitrogen. However, the similarity of the observed ^{31}P NMR chemical shifts for **4.2** in both C_6D_6 and d_8 -THF suggests only a weak solvation interaction between **4.2** and the donating solvent.

In contrast to the deformed O,N,O-iminophosphoranes, dimerization of the constrained N,N,N-iminophosphorane **4.4** was not observed under the same conditions, probably due to the less Lewis acidic phosphorus center and more congested environment around the P=N bond introduced by the N-methylanilide groups.

4.5 B-H and B-O Additions to Distorted Iminophosphorane

We were interested in the reactivity of iminophosphoranes **4.2** and **4.4** toward hydridic E-H bonds in order to probe reactivity of the P=N unit. Borane B-H bonds are excellent candidates for probing this potential reactivity because the Lewis-acidic boron atom can easily interact with the Lewis-basic iminophosphorane nitrogen and facilitate the hydride transfer from B-H to the phosphorus center. Indeed, even with the weakly hydridic pinacolborane, compound **4.2** undergoes an immediate B-H addition across the P=N bond (**Figure 4.13 top**). The resulting ^{31}P NMR spectrum of this reaction shows a doublet of triplets centered at -43.7 ppm with a coupling constants $^1J_{\text{P-H}} = 837$ Hz and $^3J_{\text{P-H}} = 33$ Hz, consistent with the formation of a pentacoordinate hydridophosphorane. Complementarily, the existence of a P-H moiety is confirmed by ^1H NMR spectroscopy, with a doublet centered at 9.37 ppm ($^1J_{\text{P-H}} = 837$ Hz). N,N,N-iminophosphorane **4.4** similarly gives B-H addition with pinacolborane despite the lack of dimerization reactivity. To the best of our knowledge, no iminophosphorane has been previously reported to react with the borane B-H bonds to give the corresponding σ^5 -hydridophosphorane. The reactivity of **4.2** and **4.4** toward B-H bonds demonstrate the hypothesized reactivity of the strained phosphabicyclic iminophosphoranes.

Figure 4.13. B-H additions to **4.2** and **4.4** with pinacolborane. dipp = 2,6-diisopropylphenyl.

With the distorted geometry, O,N,O-iminophosphorane **4.2** exhibits unusual Lewis-acidic reactivity toward B-O bonds of $\text{B}(\text{OMe})_3$ and butoxy catecholborane (**Figure 4.14**). Reacting **4.2** with 1 equiv. of trimethyl borate produces a phosphorus species with a triplet at -41.2 ppm in ^{31}P NMR spectra ($J = 31$ Hz) (**Figure 4.14 bottom**). ^1H NMR of this product also showed a doublet at 5.52 ppm ($J = 31$ Hz), corresponding to the ligand vinylic protons of the O,N,O-phosphobicyclic ligand. The characteristic ^{31}P NMR chemical shift and the small $^3J_{\text{P-H}}$ coupling of this product indicate that B-O addition across the P=N bond of **4.2** has occurred and the formation of a σ^5 -phosphorus compound **4.15**. The reactivity of **4.2** toward B-O bonds is further demonstrated by reacting **4.2** with *n*-butoxy catecholborane (**Figure 4.14 bottom**). Product **4.16** of this reaction again showed a triplet resonance centered at -31.4 ppm ($^3J_{\text{P-H}} = 17$ Hz) in ^{31}P NMR spectra. X-ray diffraction of the isolated **4.16** confirmed the σ^5 -phosphorus

structure of this B-O addition product (**Figure 4.15**). The structure of **4.16** contains a *n*-butoxy group attached to the phosphorus center and a catecholboryl group on the amido nitrogen. The O,N,O-phosphabicyclic backbone of **4.2** has turned into part of the trigonal pyramidal structure and the phosphabicyclic nitrogen N(1) and the butoxy oxygen O(3) occupy the apical positions. The preference of placing the N(1) rather than two oxygen on the apical positions is probably due to the interaction between N(1) and the catecholboryl boron atom B(1), which renders N(1) even more electron-deficient than the phosphabicyclic oxygens. The N(1) - B(1) interaction can be confirmed by the short B-N distance (1.634(3) Å). These transformations demonstrated the first example of σ^4 -iminophosphorane mediated B-O activation and provide further evidence for geometry-induced reactivity enhancement on the phosphorus atom.

Figure 4.14. B-O additions to O,N,O-iminophosphorane **4.2**. dipp = 2,6-diisopropylphenyl.

Figure 4.15. Molecular structure of **4.16** with 50% probability level rendered thermal ellipsoid plot.

4.6 Si-H Addition to Distorted Iminophosphoranes

Hydrosilanes are not generally as reactive as boranes due to the lack of non-bonding orbitals on the silicon atom with which to accept an incoming nucleophile and increase hydricity. However, reacting phenylsilane with 1 equiv. of iminophosphorane **4.2** in C_6D_6 at 50 °C for 16 h (**Figure 4.16**) gives a phosphorus species **4.17** with a characteristic doublet resonance centered at 9.44 ppm in 1H NMR spectra exhibiting a large coupling constant ($^1J_{P-H} = 802$ Hz), indicative of the existence of a P-H bond. Two other 1H NMR doublet signals at 5.53 and 5.40 ppm represent P-H coupled vinyl protons and SiH_2 protons, respectively. The ^{31}P NMR spectra also show a doublet of triplets centered at -44.2 ppm with coupling constants of 803 Hz and 30 Hz. Taken together, the

product NMR spectra suggests that the silane Si-H bond has added across the P=N bond of **4.2** resulting in a hydridophosphorane with an N-silyl substituent. N,N,N-iminophosphorane **4.4** also reacts with phenylsilane but more slowly. The conversion of **4.4** and phenylsilane to hydridophosphorane **4.18** is completed after 48 hour of 80 °C heating in C₆D₆. The resulting ³¹P NMR spectrum demonstrates again a signal centered at -29.1 ppm with a characteristic ¹J_{P-H} = 535 Hz, consistent with the structure of the σ⁵-phosphorus Si-H addition product.

Figure 4.16. B-O additions to O,N,O-iminophosphorane **4.2**. dipp = 2,6-diisopropylphenyl.

In addition to the reaction with iminophosphorane **4.2** under mild conditions, phenylsilane also reacts with dimeric iminophosphorane **4.2a** to give complete conversion to the hydrophosphorane product, demonstrating again the monomer-dimer interconversion of **4.2/4.2a** in solution. Expanding the substrate scope to more sterically hindered silanes were attempted, but triethylsilane, triphenylsilane and diphenylsilane all gave no Si-H addition product even in refluxing toluene for several days. The low reactivity of **4.2** toward secondary or tertiary silanes may result from the steric hindrance of the *N*-dipp substituent. Attempts to react silanes with less bulky *N*-tolyl iminophosphoranes **4.7** were unsuccessful, likely because **4.7** dimerized to **4.7a** before reacting with the silanes and no monomer-dimer interconversion can regenerate monomer **4.7**. All other O,N,O-iminophosphoranes with less steric *N*-substituents behave the same as **4.7** and give no Si-H activation reactivity. The distorted N,N,N-iminophosphorane **4.4** demonstrates lower Si-H addition reactivity than **4.2** with higher reaction temperature (80 °C) being required for the transformation. Since **4.4** contains a more hindered structure around the phosphorus center and a similar P=N length with acyclic iminophosphorane **4.6**, the lower reactivity of **4.4** toward the Si-H bond is expected. Activation of Si-H bonds by **4.2** and **4.4** gives direct evidence for the distinctive chemical behaviour resulting from the molecular distortion of iminophosphorane and adds another example to our ongoing research of deformed phosphorus molecules.

4.7 Conclusion and Outlook

Geometrically distorted iminophosphoranes with the strained O,N,O- and N,N,N-phosphabicyclic frameworks are synthesized from the corresponding deformed phosphines. Their structures are characterized by X-ray diffraction and compared to acyclic iminophosphoranes without constrained structures. In line with the deviated molecular geometries and the modified electronic structures, these distorted iminophosphoranes display unusual reactivities such as rapid dimerization and hydridic E-H bonds additions. Intermolecular B-H, B-O and Si-H additions across the P=N bond of the iminophosphoranes are demonstrated and the resulting σ^5 -phosphorus products are identified. Inspired by the significant property change induced by the molecular distortion in the iminophosphoranes, structure and reactivity of other σ^4 -phosphorus compounds with similar deformed frameworks are currently under investigation.

4.8 Experimental

General Materials and Methods

All reagents were purified as described in the previous chapter. Pinacolborane was purified by vacuum distillation (60 torr) and stored in a nitrogen-filled glovebox. Benzylamine was purified by distillation from zinc dust and stored over 3 Å molecular sieves prior to use. All glassware was oven-dried at 120 °C prior to use. All reactions

were carried under dry nitrogen atmosphere (Schlenk line or glovebox) unless otherwise noted. NMR spectra were recorded on a Bruker AV-360 (360MHz), a Bruker AV-400 (400 MHz), a Bruker AV-500 (500MHz) or a VARIAN Inova-500 (500MHz) spectrometer. ^1H NMR chemical shifts are given in ppm with respect to solvent residual peak (C_6D_6 , δ 7.16 ppm; CDCl_3 , δ 7.26 ppm; CD_2Cl_2 , δ 5.32 ppm), $^{13}\text{C}\{^1\text{H}\}$ NMR shifts are given in ppm with respect to CDCl_3 (δ 77.16 ppm), C_6D_6 (δ 128.06 ppm) or CD_2Cl_2 (δ 53.84 ppm). Coupling constants are reported as J -values in Hz. High resolution EI and ESI mass spectra were obtained from the Mass Spectrometry Laboratory at the School of Chemical Sciences, University of Illinois at Urbana-Champaign or Department of Chemistry Instrumentation Facility, Massachusetts Institute of Technology.

Synthetic Procedures and Characterization Data

Phosphine **4.1** and **4.3** were prepared by minor modification of the literature **Error! Bookmark not defined.** method as described in the previous chapters.

A C_6D_6 solution of **4.1** (100 mg, 0.42 mmol) was added 2,6-diisopropylphenyl azide (85 mg, 0.42 mmol) and the reaction was stirred at 40 $^\circ\text{C}$ for 16 h. All volatiles were removed *in vacuo* and the resulting residue was triturated with pentane. The crude product was obtained after filtration and pure **4.2** was isolated as a white solid by recrystallization from a 10:1 dichloromethane/pentane solution (131 mg, 75 % yield). ^1H NMR (C_6D_6 , 400 MHz): δ 7.23-7.21 (m, 2H), 7.12-7.07 (m, 1H), 7.07 (d, 1H, $J = 7.7$ Hz), 5.49 (d, 2H, $J =$

28.8 Hz), 3.83 (hept, 1H, $J = 6.9$ Hz), 1.40 (d, 12H, $J = 6.8$ Hz), 0.91 (s, 18H) ppm. ^{13}C NMR (C_6D_6 , 126 MHz): δ 154.19, 141.29 (d, $J = 8.7$ Hz), 123.03, 121.98, 112.43 (d, $J = 10.1$ Hz), 32.64 (d, $J = 8.6$ Hz), 29.35, 26.89, 23.75 ppm. ^{31}P NMR (C_6D_6 , 162 MHz): δ 7.21 (t, $J = 28.8$ Hz) ppm. MS (ESI) calcd for $\text{C}_{24}\text{H}_{37}\text{N}_2\text{O}_2\text{P}$ (M^+) 416.2593 found 416.2596.

Treatment of **4.3** (100 mg, 0.39 mmol) with 1 equiv. 2,6-diisopropylphenyl azide (80 mg, 0.39 mmol) in C_6D_6 (1 ml) under ambient temperature for 12 h. The solvent was removed *in vacuo* and the resulting solid product was recrystallized from a 10:1 dichloromethane/pentane solution (121 mg, 72 % yield). ^1H NMR (C_6D_6 , 400 MHz): δ 7.26 (d, $J = 7.7$ Hz, 2H), 7.16 (d, $J = 7.4$ Hz, 2H), 7.09 – 7.02 (m, 1H), 6.98 – 6.85 (m, 3H), 6.77 (d, $J = 7.6$ Hz, 3H), 6.23 (d, $J = 7.7$ Hz, 2H), 3.65 (hept, $J = 6.9$ Hz, 2H), 2.73 (d, $J = 9.2$ Hz, 6H), 1.22 (d, $J = 6.9$ Hz, 12H) ppm. ^{13}C NMR (C_6D_6 , 125 MHz): δ 141.38, 141.00 (d, $J = 11.7$ Hz), 138.09 (d, $J = 17.6$ Hz), 134.58 (d, $J = 13.0$ Hz), 124.56, 123.26, 121.34, 120.14, 116.34 (d, $J = 10.2$ Hz), 108.66 (d, $J = 10.0$ Hz), 29.29 (d, $J = 18.9$ Hz), 23.75 ppm. ^{31}P NMR (C_6D_6 , 162 MHz): δ 14.54 ppm. MS (ESI) calcd for $\text{C}_{26}\text{H}_{31}\text{N}_4\text{P}$ (M^+) 430.2286 found 430.2290.

Treating **4.2** (30 mg, 0.07 mmol) with a C_6D_6 solution (0.3ml) of HBpin (9 mg, 0.07 mmol) at ambient temperature for 15 min. The solvent was

removed *in vacuo* to afford the crude product (37 mg, 95 % crude yield). ^1H NMR (C_6D_6 , 500 MHz): δ 9.38 (d, 1H, $J = 837.7$ Hz), 7.27 – 7.25 (m, 1H), 7.08 – 7.04 (m, 2H), 5.49 (d, 2H, $J = 33.2$ Hz), 3.62-3.56 (m, 2H), 1.53 (d, 6H, $J = 6.6$ Hz), 1.45 (d, 6H, $J = 6.6$ Hz, 6H), 1.19 (s, 12H), 1.15 (s, 18H) ppm. ^{13}C NMR (C_6D_6 , 126 MHz): δ 150.73 (d, $J = 6.4$ Hz), 147.14, 126.64, 124.52 (d, $J = 4.4$ Hz), 124.02, 123.42, 100.51 (d, $J = 18.8$ Hz), 82.52, 31.69, 28.25, 27.51, 24.66, 23.62, 23.26 ppm. ^{31}P NMR (C_6D_6 , 203 MHz): δ -43.02 (dt, $J = 837.0, 31.5$ Hz) ppm. MS (ESI) calcd for $\text{C}_{30}\text{H}_{49}\text{BN}_2\text{O}_4\text{P}$ (M-H^+) 543.3518 found 543.3523.

4.14

Treating **4.4** (35 mg, 0.08 mmol) with a C_6D_6 solution (0.3ml) of HBpin (10 mg, 0.08 mmol) at ambient temperature for 15 min. The solvent was removed *in vacuo* to afford the crude product (42 mg, 92 % crude yield). ^1H NMR (C_6D_6 , 500 MHz): δ 7.44 (d, $J = 7.5$ Hz, 2H), 7.10 – 6.85 (m, 8H), 6.56 (d, $J = 7.4$ Hz, 1H), 6.36 (d, $J = 578.8$ Hz, 1H), 3.11 – 2.91 (m, 2H), 2.60 (d, $J = 16.7$ Hz, 6H), 1.15 (d, $J = 6.9$ Hz, 6H), 1.01 (d, $J = 6.7$ Hz, 6H), 0.83 (s, 12H) ppm. ^{13}C NMR (C_6D_6 , 126 MHz): δ 147.97 (d, $J = 5.0$ Hz), 135.98, 134.16 (d, $J = 12.9$ Hz), 133.81 (d, $J = 14.5$ Hz), 126.90, 124.52 (d, $J = 5.7$ Hz), 123.11, 119.83, 118.86, 110.92 (d, $J = 11.4$ Hz), 108.55 (d, $J = 7.2$ Hz), 81.95, 28.15, 25.94, 24.61, 23.97, 23.07 ppm. ^{31}P NMR (C_6D_6 , 203 MHz): δ -37.57 (d, $J = 578.8$) ppm. MS (ESI) calcd for $\text{C}_{32}\text{H}_{43}\text{BN}_4\text{O}_2\text{P}$ (M-H^+) 557.3217 found 557.3212.

4.16

Treating **4.2** (60 mg, 0.14 mmol) with a C₆D₆ solution (0.3ml) of butoxy catecholborane (26 mg, 0.14 mmol) at ambient temperature for 1 hr. The solvent was removed *in vacuo* and the resulting solid product was recrystallized from a benzene solution (58 mg, 65 % yield). ¹H NMR (C₆D₆, 400 MHz): δ 7.15 (d, *J* = 1.5 Hz, 3H), 6.90 (dd, *J* = 5.6, 3.4 Hz, 2H), 6.67 (dd, *J* = 5.6, 3.3 Hz, 2H), 5.33 (d, *J* = 16.6 Hz, 2H), 4.05 – 3.90 (m, 2H), 3.84 – 3.71 (m, 2H), 1.52 (d, *J* = 6.8 Hz, 6H), 1.41 (d, *J* = 7.1 Hz, 6H), 1.24 – 1.10 (m, 4H), 1.04 (s, 9H), 0.87 (t, *J* = 7.4 Hz, 3H) ppm. ¹³C NMR (C₆D₆, 126 MHz): δ 157.24, 151.97, 147.15 (d, *J* = 6.0 Hz), 134.07 (d, *J* = 8.2 Hz), 126.78, 124.02, 123.38, 119.33, 109.54, 109.33 (d, *J* = 4.7 Hz), 65.24 (d, *J* = 9.2 Hz), 32.56 (d, *J* = 10.1 Hz), 27.98, 26.40, 24.85, 18.46, 15.29, 13.34 ppm. ³¹P NMR (C₆D₆, 203 MHz): δ -31.41 ppm. MS (ESI) calcd for C₃₄H₅₀BN₂O₅P (M⁺) 608.3550 found 608.3555.

4.17

Treating **4.2** (60 mg, 0.14 mmol) with a C₆D₆ solution (0.3ml) of phenylsilane (16 mg, 0.14 mmol) at 50 °C for 16 h. All volatiles were removed *in vacuo* to afford **4.17** as colorless oil (74 mg, 98 % crude yield). ¹H NMR (C₆D₆, 500 MHz): δ 9.25 (d, *J* = 801.2 Hz, 1H), 7.85 (dd, *J* = 7.9, 1.7 Hz, 2H), 7.17 – 6.85 (m, 6H), 5.34 (d, *J* = 31.2 Hz, 2H), 5.22 (s, 2H), 3.63 (hept, *J* = 6.8 Hz, 2H), 1.29 (d, *J* = 6.9 Hz, 6H), 1.08 (d, *J* = 6.8 Hz, 6H), 0.85 (s, 18H) ppm. ¹³C NMR (C₆D₆, 126 MHz): δ 150.26, 146.86, 140.12, 134.80, 129.54, 126.36, 123.82, 101.61 (d, *J* = 18.5 Hz), 31.85, 28.70, 28.22, 27.42 ppm. ³¹P NMR

(C₆D₆, 203 MHz): δ -43.52 (dt, $J = 801.8, 30.7$ Hz) ppm. MS (ESI) calcd for C₃₀H₄₆N₂O₂PSi (M+H⁺) 525.3061 found 525.3065.

4.18

Reacting **4.4** (50 mg, 0.12 mmol) with a C₆D₆ solution (0.3ml) of phenylsilane (13 mg, 0.12 mmol) at 80 °C for 48 h. All volatiles were removed *in vacuo* to afford **4.18** as yellow oil (62 mg, 99 % crude yield). ¹H NMR (C₆D₆, 500 MHz): δ 7.32 (d, $J = 7.1$ Hz, 2H), 7.14 – 6.99 (m, 7H), 6.95 (t, $J = 7.2$ Hz, 3H), 6.87 (t, $J = 7.7$ Hz, 2H), 6.73 (t, $J = 7.8$ Hz, 2H), 6.37 (d, $J = 7.5$ Hz, 2H), 5.75 (d, $J = 534.0$ Hz, 1H), 5.05 (d, $J = 5.8$ Hz, 2H), 3.45 – 3.33 (m, 2H), 2.49 (d, $J = 15.9$ Hz, 6H), 1.15 (d, $J = 6.8$ Hz, 6H), 1.06 (d, $J = 6.7$ Hz, 6H) ppm. ¹³C NMR (C₆D₆, 126 MHz): δ 148.30 (d, $J = 5.8$ Hz), 137.93, 135.77 (d, $J = 10.4$ Hz), 134.65 (d, $J = 14.5$ Hz), 134.25, 133.46, 129.01, 127.16 (d, $J = 3.6$ Hz), 123.90 (d, $J = 4.0$ Hz), 121.42, 119.38, 113.89 (d, $J = 10.8$ Hz), 108.72 (d, $J = 7.6$ Hz), 29.69 (d, $J = 15.5$ Hz), 27.61, 26.24, 23.84 ppm. ³¹P NMR (C₆D₆, 203 MHz): δ -28.54 (dt, $J = 534.5, 17.2$ Hz) ppm. MS (ESI) calcd for C₃₂H₄₀N₄PSi (M+H⁺) 539.2760 found 539.539.2763.

I. Crystallographic Procedure and Data.

A colorless block shaped crystal of **2.5e** ($C_{21}H_{33}N_2O_2P$) with approximate dimensions 0.15 x 0.16 x 0.18 mm was prepared by crystallization from pentane at $-30\text{ }^\circ\text{C}$ used for the X-ray crystallographic analysis. The X-ray intensity data were measured at 173(2) K, cooled by Rigaku-MSX X-Stream 2000, on a Bruker SMART APEX CCD area detector system equipped with a graphite monochromator and a MoKa fine-focus sealed tube ($\lambda = 0.71073\text{ \AA}$) operated at 1600 watts power (50 kV, 32 mA). The detector was placed at a distance of 5.8 cm from the crystal. A total of 1750 frames were collected with a scan width of 0.3° in ω and an exposure time of 10 seconds/frame. The total data collection time was about 8 hours. The frames were integrated with the Bruker SAINT software package using a narrow-frame integration algorithm. The integration of the data using a Monoclinic unit cell yielded a total of 17228 reflections to a maximum θ angle of 28.19° (0.90 \AA resolution), of which 5154 were independent, completeness = 98.9%, $R_{\text{int}} = 0.0303$, $R_{\text{sig}} = 0.0321$ and 4342 were greater than $2s(I)$. The final cell constants: $a = 14.8761(19)\text{ \AA}$, $b = 17.428(2)\text{ \AA}$, $c = 8.2778(10)\text{ \AA}$, $\alpha = 90^\circ$, $\beta = 99.402(2)^\circ$, $\gamma = 90^\circ$, volume = $2117.3(5)\text{ \AA}^3$, are based upon the refinement of the XYZ-centroids of 7582 reflections above $2\sigma(I)$ with $2.718^\circ < \theta < 28.172^\circ$. Analysis of the data showed negligible decay during data collection. Data were corrected for absorption effects using the multiscan technique (SADABS). The ratio of minimum to maximum apparent transmission was 0.7794. The structure was solved and refined using the Bruker SHELXTL (Version 6.1) Software Package, using the space group $P2(1)/c$, with $Z = 4$ for the formula unit, $C_{21}H_{33}N_2O_2P$. Hydrogen atoms on P1 and N2 were located from difference Fourier map and were refined isotropically. Rest of the hydrogen atoms were placed geometrically at chemically meaningful positions. The hydrogen atoms of the phenyl ring were allowed to ride at a distance of 0.93 \AA from the parent carbons and their

thermal parameter were fixed at 1.2 times that of the parent atom. The secondary CH₃ hydrogen atoms were fixed at a distance of 0.96 Å from the parent atom and their thermal parameters were fixed at 1.5 times the parent atom. The final anisotropic full-matrix least-squares refinement on F² with 252 variables converged at R1 = 4.38%, for the observed data and wR2 = 12.71% for all data. The goodness-of-fit was 1.070. The largest peak on the final difference map was 0.460 e⁻/Å³ and the largest hole was -0.256 e⁻/Å³. Based on the final model, the calculated density of the crystal is 1.181 g/cm³ and F(000) amounts to 816 electrons.

II. Kinetics Data.

All kinetics experiments were conducted on the oxidative addition reaction of *n*-propylamine to **2.3** (**Figure A1**). Compound **2.3** was recrystallized from pentane three times then stored in a nitrogen-filled glovebox before use. *n*-Propylamine was distilled twice from zinc dust then stored in a nitrogen-filled glovebox before use. Benzene and pentane were dried by passage over an activated alumina column.

Figure A1. Oxidative addition of *n*-propylamine to **2.3**.

Time-stacked UV-vis spectra (Figure 2.15A). Measurements were performed on a Hewlett-Packard 8453 spectrophotometer with a Hewlett-Packard 8909DA peltier-thermostatted cuvette holder. A stock solution of compound **1** (3 mL, 0.27 mM in pentane) was added to a screw-top quartz cuvette (1 cm pathlength) fitted with a threaded septum. An initial UV-vis absorbance spectrum ($225 \text{ nm} < \lambda < 400 \text{ nm}$) was recorded. *n*-Propylamine (0.2 mL, 2250 equiv.) was then added via syringe and spectra were collected at 30 s intervals over the course of 5 min. The spectra (Figure 12A) show the consumption of **1** ($\lambda_{\text{max}} = 313 \text{ nm}$) and an increase in absorbance at lower wavelengths consistent with the formation of $\mathbf{1}\cdot[\text{H}][\text{NH}^n\text{Pr}]$ (the absorbance maximum of $\mathbf{1}\cdot[\text{H}][\text{NH}^n\text{Pr}]$ ($\lambda_{\text{max}} = 239 \text{ nm}$) is obscured by the tail from the excess *n*-PrNH₂). An isosbestic point is evident at $\lambda = 272 \text{ nm}$.

Pseudo-first order kinetics (Figure 2.15B). Measurements were performed on a Hitachi Digilab U-3010 spectrophotometer equipped with a cuvette holder thermostatted by a VWR 1140S water circulator. A stock solution of compound **1** (3 mL, 0.31 mM in benzene) was added to a screw-top quartz cuvette (1 cm pathlength) fitted with a threaded septum. The cuvette was placed in the temperature controlled spectrometer cell holder (25 °C) and allowed to thermally equilibrate for 10 min. Absorbance data were then collected at $\lambda = 314$ nm for ca. 15 seconds to establish a $t = 0$ baseline value. *n*-Propylamine (0.2 mL, 2250 equiv.) was then added via syringe and spectra were collected at 0.2 s intervals over the course of 500 s.

Determination of reaction order in amine (Figure 2.16). Measurements were performed on a Hitachi Digilab U-3010 spectrophotometer equipped with a cuvette holder thermostatted by a VWR 1140S water circulator. A stock solution of compound **1** (3 mL, 0.31 mM in benzene) was added to a screw-top quartz cuvette (1 cm pathlength) fitted with a threaded septum. The cuvette was placed in the temperature controlled spectrometer cell holder (25 °C) and allowed to thermally equilibrate for 10 min. Absorbance data were then collected at $\lambda = 314$ nm for ca. 15 seconds to establish a $t = 0$ baseline value. *n*-Propylamine solutions of varying concentrations (0.2 mL, 0.06 to 10.33 M, 14 to 2222 equiv.) were then added via syringe and spectra were collected at 0.2 s intervals over the course of 500 s. The observed pseudo-first order rate constant (k_{obs}) was extracted from an average of three independent runs at each concentration.

Table A5. Effect of amine concentration on observed rate.

$[n\text{-PrNH}_2]$ (M)	$[n\text{-PrNH}_2]^2$ (M ²)	$[n\text{-PrNH}_2]^3$ (M ³)	k_{obs} (s ⁻¹)

Eyring kinetics. Measurements were performed on a Hitachi Digilab U-3010 spectrophotometer equipped with a cuvette holder thermostatted by a VWR 1140S water circulator. A stock solution of compound **1** (3 mL, 0.31 mM in benzene) was added to a screw-top quartz cuvette (1 cm pathlength) fitted with a threaded septum. The cuvette was placed in the temperature controlled spectrometer cell holder and allowed to thermally equilibrate for 10 min to a series of temperatures (10 to 70 °C). Absorbance data were then collected at $\lambda = 314$ nm for ca. 15 seconds to establish a $t = 0$ baseline value. *n*-Propylamine (0.2 mL, 2613 equiv.) was then added via syringe and spectra were collected at 0.2 s intervals over the course of 500 s. The observed pseudo-first order rate constant (k_{obs}) was extracted from an average of three to six independent runs at each temperature.

Table A6. Eyring data.

Temp (K)	1/T (K ⁻¹)	k (s ⁻¹ M ⁻³)	ln(k/T)

Note: Though the amidophosphanide/ammonium ion pair intermediate is slightly more unstable than TS2 on the entropy and free energy surface, it is more stable by 1.5 kcal/mol on the SCF energy surface. This indicates the shallow nature of the energy surface connecting TS2 and TS3 and also consistent with the experimentally unobservable intermediate.

NBO Analysis. Calculations were carried out using the Gaussian09 (rev b1) suite of programs¹ running on Intel X5670 2.93 GHz processors located at the Research Computing and Cyberinfrastructure Unit of Information Technology Services at the Pennsylvania State University. With the M06-2X functional and 6-31G** basis set, NBO analysis² of isolated gas phase **2.5e** was performed using coordinates obtained from the crystallographically determined structure. Orbital surfaces (isovalue 0.04) were plotted with Gaussview 5.

I. NOESY Experiments for Characterization of Compound 3.6

All NOE NMR spectra were obtained on a Bruker Avance 500 MHz NMR spectrometer equipped with a 5mm broadband, BBFO Z-gradient probe. The samples were *in situ* generated **3.6** from compound **3.2** and pinacolborane in C_6D_6 (1.3×10^{-2} M).

Full spectrum:

Correlation signals between aliphatic protons:

Correlation signals between aliphatic protons and aromatic protons:

II. *In Situ* ^{31}P NMR for the Reaction of Compound 3.6 with chloroform

Under nitrogen atmosphere, pinacolborane (10 mg, 0.08 mmol) was mixed with a C_6D_6 solution (0.6 mL) of compound **3.6** (20 mg, 0.08 mmol) in a J-Young NMR tube. The mixture was kept at 50°C for 12 h to generate crude **3.7**. A C_6D_6 solution of CDCl_3 (0.2 ml, 42 mM) was then added. The reaction mixture was then monitored by ^{31}P NMR after 15 min, 2 h and 4 h under ambient temperature.

III. Kinetic Study of the B-H Activation Reaction

Pseudo-first order kinetics. Experiments were conducted with varying equivalent of HBPin with at least 10-fold excess. Measurements were performed on a Bruker AV-400 NMR spectrometer. A stock solution of compound **3.2** (0.6 ml, 13 mM in C_6D_6 containing 0.06 mmol 1,3,5-trimethoxybenzene as the internal standard) and HBpin were added to a volumetric flask and the resulting mixture was diluted to 1 ml with C_6D_6 . The diluted solution was then transferred to a J-Young NMR tube and the conversion of **3.2** to **3.6** was monitored with 1H NMR at ambient temperature. The concentrations of **3.2** were obtained from the NMR signal integral ratios between **3.2** and the internal standard. The error bars on the plot are generated from variability of 1H NMR integrals.

Table B1. Pseudo-first order rate constant in varying equivalent of HBpin.

HBpin equiv.	[HBpin]	k_{obs} (s^{-1})
10	0.78	0.002228
15	1.17	0.002440
20	1.56	0.002875
25	1.95	0.003072
30	2.34	0.003427
35	2.73	0.003733

Determination of reaction order in HBpin. The observed pseudo-first order rate constants (k_{obs}) were plotted against the corresponding HBpin concentrations (0.78 M – 2.73 M).

IV. Kinetic Study of the B-N Elimination Reaction

In a nitrogen-filled glovebox, a 1:1 THF/ether solution (2 ml) of **3.7** (10 mg, 2.39×10^{-2} mmol) and an ether solution (1 ml) of *N*-benzyl-1-(4-methoxyphenyl)methanamine (12 mg, 4.79×10^{-2} mmol) were both cooled to -30 °C and then mixed together. The resulting cloudy mixture was quickly filtered through Celite and all volatiles were removed in vacuo to afford crude **3.10**. (NMR yield 82 %). The crude product was dissolved in 1 mL of C₆D₆ containing 1,3,5-trimethoxybenzene (2 mg, 1.9×10^{-2} mmol) and the conversion of **3.10** to **3.2** and the *N*-borylamine **7** was monitored by ¹H NMR spectroscopy, with the varying concentrations of **3.10** and **3.2** determined at regular time intervals by ¹H NMR integration relative to internal standard. The error bars on the plot are generated from variability of ¹H NMR integrals.

V. General Synthetic Procedure for Imines¹

Aldimines. In a two-neck round-bottom flask equipped with Dean-Stark apparatus, a toluene solution (20 ml) of the aldehyde (0.02 mol) was added the amine (0.02 mol). The mixture was refluxed and the reaction progress was monitored by thin layer chromatography. Upon completion, the solution was filtered through Celite and all volatiles were removed *in vacuo*. The resulting solid product was purified by recrystallization from ethanol.

Ketimines. In a two-neck round-bottom flask equipped with Dean-Stark apparatus, a toluene solution (20 ml) of the ketone (0.02 mol) was added the amine (0.02 mol) and sodium bicarbonate (0.02 mol). The mixture was refluxed and the reaction progress was monitored by thin layer chromatography. Upon completion, the solution was filtered through Celite and all volatiles were removed *in vacuo*. The resulting solid product was purified by recrystallization from ethanol.

VI. Catalytic Experiments and Characterization Data

A C₆D₆ solution (0.6 ml) of compound **3.2** (1.50×10^{-2} mmol) was added the imine (0.15 mmol) and HBpin (0.19 mmol). The mixture was then added 10 mg of 1,3,5-trimethoxybenzene as the internal standard and transferred to a J-Young NMR tube. The reaction solution was kept under 50 °C for 24 hours and the conversion of was monitored by ¹H NMR. The concentrations and yields of the product borylamine were obtained from the NMR signal integral ratios between the borylamine and the internal standard.

3.11. ¹H NMR (360 MHz, C₆D₆) δ 7.93, 7.43 (d, 2H, *J* = 7.6 Hz), 7.38 – 7.20 (m, 6H), 6.94 (d, 2H, *J* = 7.6 Hz), 5.37, 4.30 (s, 2H), 4.25 (s, 2H), 3.46 (s, 3H), 1.32(s, 12H). MS (ESI+) calcd for C₂₁H₂₈NO₃ (M) 353.2162 found 353.2165.

3.15a. ¹H NMR (360 MHz, C₆D₆): δ 7.49 (d, 2H, *J* = 7.9 Hz); 7.23 (d, 2H, *J* = 7.4 Hz); 7.14-7.09(m, 6H); 4.78(s, 2H); 1.08(s, 12H) ppm. MS (ESI+) calcd for C₁₃H₁₂N (M-Bpin) 182.0970 found 182.0968.

3.16a. ¹H NMR (360 MHz, C₆D₆): δ 7.25(d, 2H, *J* = 7.2 Hz); 7.19-7.09 (m, 5H); 6.87(d, 2H, *J* = 7.2 Hz); 4.03(s, 2H); 3.93(s, 2H); 1.15(s, 12H) ppm. MS (ESI+) calcd for C₂₀H₂₅NO₂BBr (M) 401.1162 found 401.1166.

3.17a. ¹H NMR (360 MHz, C₆D₆): δ 7.40(d, 2H, *J* = 7.2 Hz); 7.20(d, 2H, *J* = 7.2 Hz); 7.01-6.91(m, 4H); 4.79(s, 2H); 2.07(s, 3H); 2.05(s, 3H); 1.10(s, 12H) ppm. MS (ESI+) calcd for C₁₅H₁₆N (M-Bpin) 210.1283 found 210.1285.

MS (EI+) calcd for $\text{C}_{15}\text{H}_{16}\text{N}$ (M-Bpin) 210.1283 found 210.1286.

VII. Crystallographic Procedures and Data

A colorless block shaped crystal of **3.7** (C₂₀ H₂₆ B Cl N₃ O₂ P) with approximate dimensions 0.29 × 0.25 × 0.24 mm, was used for the X-ray crystallographic analysis. The X-ray intensity data were measured at 213(2) K, cooled by Rigaku-MSX-Stream 2000, on a Bruker SMART APEX CCD area detector system equipped with a graphite monochromator and a MoK fine-focus sealed tube ($\lambda = 0.71073 \text{ \AA}$) operated at 1600 watts power (50 kV, 32 mA). The detector was placed at a distance of 5.82 cm from the crystal.

A total of 1850 frames were collected with a scan width of 0.3° in ω and an exposure time of 10 seconds/frame. The total data collection time was about 8 hours. The frames were integrated with the Bruker SAINT software package using a narrow-frame integration algorithm. The integration of the data using a Triclinic unit cell yielded a total of 10199 reflections to a maximum angle of

28.398 (0.90 Å resolution), of which 5223 were independent, completeness = 98.6%, $R_{\text{int}} = 0.0163$, $R_{\text{sigma}} = 0.0372$ and 4276 were greater than $2\delta(I)$. The final cell constants: $a = 8.197(4)$ Å, $b = 9.932(4)$ Å, $c = 15.016(7)$ Å, $\alpha = 90^\circ$, $\beta = 93.531(2)^\circ$, $\gamma = 68.269(11)^\circ$, volume = $1084.8(8)$ Å³, are based upon the refinement of the XYZ-centroids of 4359 reflections above $20\delta(I)$ with $4.496^\circ \leq 2\theta \leq 56.796^\circ$. Analysis of the data showed negligible decay during data collection. Data were corrected for absorption effects using the multiscan technique (SADABS). The ratio of minimum to maximum apparent transmission was 0.3144.

The structure was solved and refined using the Bruker SHELXTL (Version 6.1) Software Package, using the space group P-1, with $Z = 2$ for the formula unit, C20 H26 B Cl N3 O2 P. The final anisotropic full-matrix least-squares refinement on F^2 with 259 variables converged at $R1 = 5.71\%$, for the observed data and $wR2 = 15.86\%$ for all data. The goodness-of-fit was 1.131. The largest peak on the final difference map was $0.342 \text{ e}^-/\text{Å}^3$ and the largest hole was $-0.255 \text{ e}^-/\text{Å}^3$. Based on the final model, the calculated density of the crystal is 1.279 g/cm^3 and $F(000)$ amounts to 440 electrons.

Table B2. Fractional Atomic Coordinates ($\times 10^4$) and Equivalent Isotropic Displacement Parameters ($\text{Å}^2 \times 10^3$) for 3.7. U_{eq} is defined as 1/3 of the trace of the orthogonalised U_{ij} tensor.

A colorless block shaped crystal of **3.8** (C₃₄ H₄₀ B N₄ O₄ P S) with approximate dimensions 0.15 × 0.14 × 0.11 mm, was used for the X-ray crystallographic analysis. The X-ray intensity data were measured at 298(2) K on a Bruker SMART APEX CCD area detector system equipped with a graphite monochromator and a MoK fine-focus sealed tube (= 0.71073 Å) operated at 1600 watts power (50 kV, 32 mA). The detector was placed at a distance of 5.82 cm from the crystal.

A total of 1850 frames were collected with a scan width of 0.3° in ω and an exposure time of 10 seconds/frame. The total data collection time was about 8 hours. The frames were integrated with the Bruker SAINT software package using a narrow-frame integration algorithm. The integration of the data using a Triclinic unit cell yielded a total of 12176 reflections to a maximum angle of 28.41 (0.90 Å resolution), of which 7324 were independent, completeness = 92.3%, $R_{\text{int}} = 0.0349$,

$R_{\text{sigma}} = 0.0778$ and 5319 were greater than $2\delta(I)$. The final cell constants: $a = 10.580(2) \text{ \AA}$, $b = 10.675(2) \text{ \AA}$, $c = 15.627(4) \text{ \AA}$, $\alpha = 108.388(5)$, $\beta = 92.418(3)^\circ$, $\gamma = 90.015(4)^\circ$, volume = $1673.2(6) \text{ \AA}^3$, are based upon the refinement of the XYZ-centroids of 2764 reflections above $20\delta(I)$ with $2.316^\circ \leq \theta \leq 26.603^\circ$. Analysis of the data showed negligible decay during data collection. Data were corrected for absorption effects using the multiscan technique (SADABS). The ratio of minimum to maximum apparent transmission was 0.1257.

The structure was solved and refined using the Bruker SHELXTL (Version 6.1) Software Package, using the space group P1, with $Z = 2$ for the formula unit, C34 H40 B N4 O4 P S. The final anisotropic full-matrix least-squares refinement on F^2 with 392 variables converged at $R1 = 8.79\%$, for the observed data and $wR2 = 26.02\%$ for all data. The goodness-of-fit was 1.453. The largest peak on the final difference map was $0.715 \text{ e}^-/\text{\AA}^3$ and the largest hole was $-0.403 \text{ e}^-/\text{\AA}^3$. Based on the final model, the calculated density of the crystal is 1.275 g/cm^3 and $F(000)$ amounts to 680 electrons.

Table B8. Fractional Atomic Coordinates ($\times 10^4$) and Equivalent Isotropic Displacement Parameters ($\text{\AA}^2 \times 10^3$) for 3.8. U_{eq} is defined as 1/3 of of the trace of the orthogonalised U_{IJ} tensor.

A colorless block shaped crystal of **3.12** (C₂₇ H₃₄ B N₄ O₂ P) with approximate dimensions 0.22 × 0.17 × 0.11 mm, was used for the X-ray crystallographic analysis. The X-ray intensity data were measured at 213(2) K, cooled by Rigaku-MSX X-Stream 2000, on a Bruker SMART APEX CCD area detector system equipped with a graphite monochromator and a MoK fine-focus sealed tube ($\lambda = 0.71073 \text{ \AA}$) operated at 1600 watts power (50 kV, 32 mA). The detector was placed at a distance of 5.82 cm from the crystal.

A total of 1440 frames were collected with a scan width of 0.3° in ω and an exposure time of 10 seconds/frame. The total data collection time was about 6 hours. The frames were integrated with the Bruker SAINT software package using a narrow-frame integration algorithm. The integration of the data using a Triclinic unit cell yielded a total of 9853 reflections to a maximum angle of 28.323° (0.90 \AA resolution), of which 6281 were independent, completeness = 98.9%, $R_{\text{int}} = 0.0144$, $R_{\text{sigma}} = 0.0299$ and 5520 were greater than $2\sigma(I)$. The final cell constants: $a = 10.7971(12) \text{ \AA}$, $b = 11.4825(13) \text{ \AA}$, $c = 12.3601(14) \text{ \AA}$, $\alpha = 89.490(2)^\circ$, $\beta = 65.116(2)^\circ$, $\gamma = 71.217(2)^\circ$, volume = $1301.7(3) \text{ \AA}^3$, are based upon the refinement of the XYZ-centroids of 4458 reflections above $20\sigma(I)$ with $2.436^\circ \leq \theta \leq 28.278^\circ$. Analysis of the data showed negligible decay during data collection. Data were corrected for absorption effects using the multiscan technique (SADABS). The ratio of minimum to maximum apparent transmission was 0.8553.

The structure was solved and refined using the Bruker SHELXTL (Version 6.1) Software Package, using the space group P-1, with $Z = 2$ for the formula unit, C₂₇ H₃₄ B N₄ O₂ P. The

final anisotropic full-matrix least-squares refinement on F^2 with 326 variables converged at $R1 = 5.89\%$, for the observed data and $wR2 = 17.01\%$ for all data. The goodness-of-fit was 1.267. The largest peak on the final difference map was $0.432 \text{ e}^-/\text{\AA}^3$ and the largest hole was $-0.269 \text{ e}^-/\text{\AA}^3$. Based on the final model, the calculated density of the crystal is 1.246 g/cm^3 and $F(000)$ amounts to 520 electrons.

Table B13. Fractional Atomic Coordinates ($\times 10^4$) and Equivalent Isotropic Displacement Parameters ($\text{\AA}^2 \times 10^3$) for 3.12. U_{eq} is defined as 1/3 of of the trace of the orthogonalised U_{ij} tensor.

I. General Synthetic Procedure for Azides¹

A mixture of amine (5 mmol) and NaNO₂ (5.5 mmol) were added to a cooled (−30 °C) acidic (5 mL of concentrated HCl and 5 mL of distilled H₂O) solution of NaBF₄ (10 mmol). A yellow precipitate was gradually formed after several minutes of stirring. The mixture was then stirred at −30 °C for additional 30 min. The resulting intermediate diazonium tetrafluoroborate salt was filtered quickly in air and washed with cold water. This yellow sticky powder was added to a cooled (0 °C) aqueous solution (10 mL) of NaN₃. After vigorous gas evolution, the orange mixture was stirred overnight at 25 °C. The product was extracted from the aqueous layer with diethyl ether and dried with MgSO₄. The solution was filtered, and the solvent was removed to give the crude azide product. The crude product was dissolved in 10 ml of hexane and further purified by passing through a plug of silica gel. Hexane was removed *in vacuo* from the collected solution to afford the pure azide product.

II. Crystallographic Procedures and Data

Table C1. Crystal data and structure refinement for 4.2.

Identification code	yzl18m
Empirical formula	C ₂₅ H ₃₈ NO ₂ P

Formula weight	415.53
Temperature/K	198(2)
Crystal system	monoclinic
Space group	C2/c
a/Å	19.931(8)
b/Å	12.616(8)
c/Å	21.565(12)
α /°	90.00
β /°	109.346(14)
γ /°	90.00
Volume/Å ³	5116(5)
Z	8
$\rho_{\text{calc}}/\text{cm}^3$	1.079
μ/mm^{-1}	0.126
F(000)	1808.0
Crystal size/mm ³	0.2 × 0.15 × 0.12
Radiation	MoK α (λ = 0.71073)
2 θ range for data collection/°	3.88 to 56.76
Index ranges	-26 ≤ h ≤ 26, -16 ≤ k ≤ 11, -28 ≤ l ≤ 28
Reflections collected	18786
Independent reflections	6358 [R_{int} = 0.0309, R_{sigma} = 0.0263]
Data/restraints/parameters	6358/0/272
Goodness-of-fit on F ²	1.055
Final R indexes [$I \geq 2\sigma(I)$]	R_1 = 0.0579, wR_2 = 0.1718
Final R indexes [all data]	R_1 = 0.0667, wR_2 = 0.1819
Largest diff. peak/hole / e Å ⁻³	0.70/-0.69

Table C2. Fractional Atomic Coordinates ($\times 10^4$) and Equivalent Isotropic Displacement Parameters ($\text{\AA}^2 \times 10^3$) for 4.2. U_{eq} is defined as 1/3 of the trace of the orthogonalised U_{ij} tensor.

Experimental

Single crystals of $C_{25}H_{38}NO_2P$ [4.2] were [yzl18m]. A suitable crystal was selected and [] on a CCD area detector diffractometer. The crystal was kept at 198(2) K during data collection. Using Olex2 [1], the structure was solved with the ShelXS-1997 [2] structure solution program using Direct Methods and refined with the XL [3] refinement package using Least Squares minimisation.

Crystal Data for $C_{25}H_{38}NO_2P$ ($M = 415.53$ g/mol): monoclinic, space group C2/c (no. 15), $a = 19.931(8)$ Å, $b = 12.616(8)$ Å, $c = 21.565(12)$ Å, $\beta = 109.346(14)^\circ$, $V = 5116(5)$ Å³, $Z = 8$, $T = 198(2)$ K, $\mu(\text{MoK}\alpha) = 0.126$ mm⁻¹, $D_{\text{calc}} = 1.079$ g/cm³, 18786 reflections measured ($3.88^\circ \leq 2\theta \leq 56.76^\circ$), 6358 unique ($R_{\text{int}} = 0.0309$, $R_{\text{sigma}} = 0.0263$) which were used in all calculations. The final R_1 was 0.0579 ($>2\sigma(I)$) and wR_2 was 0.1819 (all data).

Table C8. Crystal data and structure refinement for 4.4.

Identification code	yzl19s
Empirical formula	C ₂₆ H ₃₁ N ₄ P
Formula weight	430.52
Temperature/K	223.15
Crystal system	monoclinic
Space group	P2 ₁ /n

a/Å	12.8565(18)
b/Å	9.4531(13)
c/Å	19.152(3)
$\alpha/^\circ$	90.00
$\beta/^\circ$	96.382(4)
$\gamma/^\circ$	90.00
Volume/Å ³	2313.2(6)
Z	4
$\rho_{\text{calc}}/\text{g}/\text{cm}^3$	1.236
μ/mm^{-1}	0.140
F(000)	920.0
Crystal size/mm ³	0.22 × 0.2 × 0.16
Radiation	MoK α ($\lambda = 0.71073$)
2 Θ range for data collection/ $^\circ$	4.04 to 56.6
Index ranges	-11 ≤ h ≤ 17, -12 ≤ k ≤ 12, -25 ≤ l ≤ 21
Reflections collected	15190
Independent reflections	5662 [$R_{\text{int}} = 0.0172$, $R_{\text{sigma}} = 0.0208$]
Data/restraints/parameters	5662/0/286
Goodness-of-fit on F ²	1.035
Final R indexes [$I \geq 2\sigma(I)$]	$R_1 = 0.0432$, $wR_2 = 0.1188$
Final R indexes [all data]	$R_1 = 0.0489$, $wR_2 = 0.1248$
Largest diff. peak/hole / e Å ⁻³	0.29/-0.35

Table C9. Fractional Atomic Coordinates ($\times 10^4$) and Equivalent Isotropic Displacement Parameters ($\text{\AA}^2 \times 10^3$) for 4.4. U_{eq} is defined as 1/3 of the trace of the orthogonalised U_{ij} tensor.

Experimental

Single crystals of $C_{26}H_{31}N_4P$ [4.4] were [yzl19s]. A suitable crystal was selected and [] on a CCD area detector diffractometer. The crystal was kept at 223.15 K during data collection. Using Olex2 [1], the structure was solved with the ShelXS-1997 [2] structure solution program using Direct Methods and refined with the XL [3] refinement package using Least Squares minimisation.

Crystal Data for $C_{26}H_{31}N_4P$ ($M = 430.52$ g/mol): monoclinic, space group $P2_1/n$ (no. 14), $a = 12.8565(18)$ Å, $b = 9.4531(13)$ Å, $c = 19.152(3)$ Å, $\beta = 96.382(4)^\circ$, $V = 2313.2(6)$ Å³, $Z = 4$, $T = 223.15$ K, $\mu(\text{MoK}\alpha) = 0.140$ mm⁻¹, $D_{\text{calc}} = 1.236$ g/cm³, 15190 reflections measured ($4.04^\circ \leq 2\theta \leq 56.6^\circ$), 5662 unique ($R_{\text{int}} = 0.0172$, $R_{\text{sigma}} = 0.0208$) which were used in all calculations. The final R_1 was 0.0432 ($>2\sigma(I)$) and wR_2 was 0.1248 (all data).

Table C15. Crystal data and structure refinement for 4.5.

Identification code	yzl21m
Empirical formula	C ₂₆ H ₃₃ N ₂ O ₂ P
Formula weight	436.51
Temperature/K	213(2)
Crystal system	monoclinic
Space group	P2 ₁ /n
a/Å	8.587(2)
b/Å	17.687(5)
c/Å	16.430(5)
α/°	90.00
β/°	99.539(6)
γ/°	90.00

Volume/Å ³	2460.9(12)
Z	4
$\rho_{\text{calc}}/\text{cm}^3$	1.178
μ/mm^{-1}	0.136
F(000)	936.0
Crystal size/mm ³	0.2 × 0.17 × 0.08
Radiation	MoK α ($\lambda = 0.71073$)
2 Θ range for data collection/°	3.4 to 56.6
Index ranges	-8 ≤ h ≤ 11, -16 ≤ k ≤ 23, -21 ≤ l ≤ 21
Reflections collected	14030
Independent reflections	5863 [R _{int} = 0.0291, R _{sigma} = 0.0310]
Data/restraints/parameters	5863/0/286
Goodness-of-fit on F ²	1.123
Final R indexes [I ≥ 2 σ (I)]	R ₁ = 0.0679, wR ₂ = 0.1670
Final R indexes [all data]	R ₁ = 0.0810, wR ₂ = 0.1747
Largest diff. peak/hole / e Å ⁻³	0.46/-0.24

Table C16. Fractional Atomic Coordinates ($\times 10^4$) and Equivalent Isotropic Displacement Parameters ($\text{\AA}^2 \times 10^3$) for 4.5. U_{eq} is defined as 1/3 of the trace of the orthogonalised U_{ij} tensor.

Experimental

Single crystals of C₂₆H₃₃N₂O₂P [4.5]. A suitable crystal was selected on a 'CCD area detector' diffractometer. The crystal was kept at 213(2) K during data collection. Using Olex2 [1], the structure was solved with the XS [2] structure solution program using Direct Methods and refined with the XL [3] refinement package using CGLS minimisation.

Crystal structure determination of [4.5]

Crystal Data for C₂₆H₃₃N₂O₂P (*M* = 436.51 g/mol): monoclinic, space group P2₁/n (no. 14), *a* = 8.587(2) Å, *b* = 17.687(5) Å, *c* = 16.430(5) Å, β = 99.539(6)°, *V* = 2460.9(12) Å³, *Z* = 4, *T* = 213(2) K, μ (MoK α) = 0.136 mm⁻¹, *D*_{calc} = 1.178 g/cm³, 14030 reflections measured (3.4° ≤ 2 θ ≤ 56.6°), 5863 unique (*R*_{int} = 0.0291, *R*_{sigma} = 0.0310) which were used in all calculations. The final *R*₁ was 0.0679 (>2sigma(I)) and *wR*₂ was 0.1747 (all data).

Refinement model description

Number of restraints - 0, number of constraints - unknown.

Details:

1. Fixed Uiso

At 1.2 times of:

All C(H) groups

At 1.5 times of:

All C(H,H,H) groups

2.a Ternary CH refined with riding coordinates:

C7(H7), C10(H10)

2.b Aromatic/amide H refined with riding coordinates:

C3(H3), C4(H4), C5(H5), C14(H14), C15(H15), C16(H16), C17(H17), C18(H18),
C20(H20), C21(H21), C22(H22), C23(H23), C24(H24)

2.c Idealised Me refined as rotating group:

C8(H8A,H8B,H8C), C9(H9A,H9B,H9C), C11(H11A,H11B,H11C), C12(H12A,H12B,H12C),
C25(H25A,H25B,H25C), C26(H26A,H26B,H26C)

Table C22. Crystal data and structure refinement for 4.6.

Identification code	yzl22s
Empirical formula	C ₂₄ H ₄₁ N ₄ P
Formula weight	416.58
Temperature/K	298(2)

Crystal system	monoclinic
Space group	P2 ₁ /c
a/Å	8.3589(18)
b/Å	16.491(4)
c/Å	18.049(4)
α/°	90
β/°	93.767(5)
γ/°	90
Volume/Å ³	2482.6(9)
Z	4
ρ _{calc} /g/cm ³	1.115
μ/mm ⁻¹	0.127
F(000)	912.0
Crystal size/mm ³	0.24 × 0.19 × 0.13
Radiation	MoKα (λ = 0.71073)
2θ range for data collection/°	3.348 to 56.66
Index ranges	-10 ≤ h ≤ 11, -19 ≤ k ≤ 21, -23 ≤ l ≤ 23
Reflections collected	19629
Independent reflections	6112 [R _{int} = 0.0377, R _{sigma} = 0.0479]
Data/restraints/parameters	6112/0/266
Goodness-of-fit on F ²	1.042
Final R indexes [I ≥ 2σ (I)]	R ₁ = 0.1261, wR ₂ = 0.2434
Final R indexes [all data]	R ₁ = 0.1627, wR ₂ = 0.2627
Largest diff. peak/hole / e Å ⁻³	0.40/-0.46

Table C23. Fractional Atomic Coordinates (×10⁴) and Equivalent Isotropic Displacement Parameters (Å²×10³) for 4.6. U_{eq} is defined as 1/3 of the trace of the orthogonalised U_{ij} tensor.

Experimental

Single crystals of C₂₄H₄₁N₄P [4.6]. A suitable crystal was selected on a 'CCD area detector' diffractometer. The crystal was kept at 298(2) K during data collection. Using Olex2 [1], the structure was solved with the olex2.solve [2] structure solution program using Charge Flipping and refined with the ShelXL [3] refinement package using Least Squares minimisation.

Crystal structure determination of [yzl22s]

Crystal Data for C₂₄H₄₁N₄P (*M* = 416.58 g/mol): monoclinic, space group P2₁/c (no. 14), *a* = 8.3589(18) Å, *b* = 16.491(4) Å, *c* = 18.049(4) Å, β = 93.767(5)°, *V* = 2482.6(9) Å³, *Z* = 4, *T* = 298(2) K, μ (MoK α) = 0.127 mm⁻¹, *D*_{calc} = 1.115 g/cm³, 19629 reflections measured (3.348° ≤ 2 θ ≤ 56.66°), 6112 unique (*R*_{int} = 0.0377, *R*_{sigma} = 0.0479) which were used in all calculations. The final *R*₁ was 0.1261 (*I* > 2 σ (*I*)) and *wR*₂ was 0.2627 (all data).

Refinement model description

Number of restraints - 0, number of constraints - unknown.

Details:

1. Fixed Uiso

At 1.2 times of:

All C(H) groups, All C(H,H) groups

At 1.5 times of:

All C(H,H,H) groups

2.a Ternary CH refined with riding coordinates:

C7 (H7), C10 (H10)

2.b Secondary CH2 refined with riding coordinates:

C13 (H13A,H13B), C14 (H14A,H14B), C15 (H15A,H15B), C16 (H16A,H16B), C17 (H17A,H17B), C18 (H18A,H18B), C19 (H19A,H19B), C20 (H20A,H20B), C21 (H21A,H21B), C22 (H22A,H22B), C23 (H23A,H23B), C24 (H24A,H24B)

2.c Aromatic/amide H refined with riding coordinates:

C3 (H3), C4 (H4), C5 (H5)

2.d Idealised Me refined as rotating group:

C8 (H8A,H8B,H8C), C9 (H9A,H9B,H9C), C11 (H11A,H11B,H11C), C12 (H12A,H12B,H12C)

This report has been created with Olex2, compiled on 2015.01.26 svn.r3150 for OlexSys. Please [let us know](#) if there are any errors or if you would like to have additional features.

A colorless block shaped crystal of 4.2a (C₂₄ H₃₇ N₂ O₂ P) with approximate dimensions 0.15 x 0.18 x 0.21 mm, was used for the X-ray crystallographic analysis. The X-ray intensity data were measured at 273(2) K, on a Bruker SMART APEX CCD area detector system equipped with a graphite monochromator and a MoK α fine-focus sealed tube ($\lambda = 0.71073\text{\AA}$) operated at 1600 watts power (50 kV, 32 mA). The detector was placed at a distance of 5.8 cm from the crystal.

A total of 1650 frames were collected with a scan width of 0.3° in ω and an exposure time of 20 seconds/frame. The total data collection time was about 12 hours. The frames were integrated with the Bruker SAINT software package using a narrow-frame integration algorithm. The integration of the data using a Monoclinic unit cell yielded a total of 24852 reflections to a

maximum θ angle of 28.35° (0.90 Å resolution), of which 5968 were independent, completeness = 98.0%, $R_{\text{int}} = 0.0528$, $R_{\text{sig}} = 0.0487$ and 4575 were greater than $2\sigma(I)$. The final cell constants: $a = 27.535(11)\text{Å}$, $b = 11.390(5)\text{Å}$, $c = 20.157(8)\text{Å}$, $\alpha = 90^\circ$, $\beta = 129.447(7)^\circ$, $\gamma = 90^\circ$, volume = $4882(3)\text{Å}^3$, are based upon the refinement of the XYZ-centroids of 1808 reflections above $20\sigma(I)$ with $2.274^\circ < \theta < 23.213^\circ$. Analysis of the data showed negligible decay during data collection. Data were corrected for absorption effects using the multiscan technique (SADABS). The ratio of minimum to maximum apparent transmission was 0.3627.

The structure was solved and refined using the Bruker SHELXTL (Version 6.1) Software Package, using the space group C2/c, with $Z = 8$ for the formula unit, C₂₄ H₃₇ N₂ O₂ P. The final anisotropic full-matrix least-squares refinement on F^2 with 272 variables converged at $R1 = 7.86\%$, for the observed data and $wR2 = 23.34\%$ for all data. The goodness-of-fit was 1.049. The largest peak on the final difference map was $0.608\text{ e}^-/\text{Å}^3$ and the largest hole was $-0.334\text{ e}^-/\text{Å}^3$. Based on the final model, the calculated density of the crystal is 1.133 g/cm^3 and $F(000)$ amounts to 1808 electrons.

Table C29. Sample and crystal data for 4.2a.

Identification code	yzl5	
Empirical formula	C ₂₄ H ₃₇ N ₂ O ₂ P	
Formula weight	416.53	
Temperature	273(2) K	
Wavelength	0.71073 Å	
Crystal size	0.21 x 0.18 x 0.15 mm	
Crystal habit	colorless block	
Crystal system	Monoclinic	
Space group	C2/c	
Unit cell dimensions	$a = 27.535(11)\text{ Å}$	$\alpha = 90^\circ$
	$b = 11.390(5)\text{ Å}$	$\beta = 129.447(7)^\circ$
	$c = 20.157(8)\text{ Å}$	$\gamma = 90^\circ$
Volume	$4882(3)\text{ Å}^3$	
Z	8	
Density (calculated)	1.133 g/cm^3	

Absorption coefficient	0.133 mm ⁻¹
F(000)	1808

Table C30. Data collection and structure refinement for 4.2a.

Diffractometer	CCD area detector
Radiation source	fine-focus sealed tube, MoK α
Generator power	1600 watts (50 kV, 32mA)
Detector distance	5.8 cm
Data collection method	phi and omega scans
Theta range for data collection	1.92 to 28.35°
Index ranges	-30 ≤ <i>h</i> ≤ 36, -14 ≤ <i>k</i> ≤ 15, -26 ≤ <i>l</i> ≤ 26

A colorless block shaped crystal of **4.7a** (C₃₈ H₅₄ N₄ O₄ P₂) with approximate dimensions 0.21 x 0.26 x 0.32 mm, was used for the X-ray crystallographic analysis. The X-ray intensity data were measured at 298(2) K, on a Bruker SMART APEX CCD area detector system equipped with a graphite monochromator and a MoK α fine-focus sealed tube ($\lambda = 0.71073\text{\AA}$) operated at 1600 watts power (50 kV, 32 mA). The detector was placed at a distance of 5.8 cm from the crystal.

A total of 1850 frames were collected with a scan width of 0.3° in ω and an exposure time of 10 seconds/frame. The total data collection time was about 8 hours. The frames were integrated with

the Bruker SAINT software package using a narrow-frame integration algorithm. The integration of the data using a Monoclinic unit cell yielded a total of 30213 reflections to a maximum θ angle of 28.42° (0.90 \AA resolution), of which 10085 were independent, completeness = 98.5%, $R_{\text{int}} = 0.0337$, $R_{\text{sig}} = 0.0450$ and 7052 were greater than $2\sigma(I)$. The final cell constants: $a = 9.2449(12)\text{\AA}$, $b = 21.052(3)\text{\AA}$, $c = 20.977(3)\text{\AA}$, $\alpha = 90^\circ$, $\beta = 94.271(2)^\circ$, $\gamma = 90^\circ$, volume = $4071.3(10)\text{\AA}^3$, are based upon the refinement of the XYZ-centroids of 5650 reflections above $20\sigma(I)$ with $2.411^\circ < \theta < 25.944^\circ$. Analysis of the data showed negligible decay during data collection. Data were corrected for absorption effects using the multiscan technique (SADABS). The ratio of minimum to maximum apparent transmission was 0.7582.

The structure was solved and refined using the Bruker SHELXTL (Version 6.1) Software Package, using the space group $P2(1)/n$, with $Z = 4$ for the formula unit, $C_{38}H_{54}N_4O_4P_2$. The final anisotropic full-matrix least-squares refinement on F^2 with 447 variables converged at $R_1 = 8.05\%$, for the observed data and $wR_2 = 23.90\%$ for all data. The goodness-of-fit was 1.100. The largest peak on the final difference map was $0.764 \text{ e}^-/\text{\AA}^3$ and the largest hole was $-0.286 \text{ e}^-/\text{\AA}^3$. Based on the final model, the calculated density of the crystal is 1.130 g/cm^3 and $F(000)$ amounts to 1488 electrons.

Table C37. Sample and crystal data for 4.7a.

Identification code	yz11	
Empirical formula	$C_{38}H_{54}N_4O_4P_2$	
Formula weight	692.79	
Temperature	298(2) K	
Wavelength	0.71073 \AA	
Crystal size	0.32 x 0.26 x 0.21 mm	
Crystal habit	colorless block	
Crystal system	Monoclinic	
Space group	$P2(1)/n$	
Unit cell dimensions	$a = 9.2449(12) \text{ \AA}$	$\alpha = 90^\circ$
	$b = 21.052(3) \text{ \AA}$	$\beta = 94.271(2)^\circ$
	$c = 20.977(3) \text{ \AA}$	$\gamma = 90^\circ$
Volume	$4071.3(10) \text{ \AA}^3$	
Z	4	
Density (calculated)	1.130 g/cm^3	

Absorption coefficient	0.147 mm ⁻¹
F(000)	1488

Table C38. Data collection and structure refinement for 4.7a.

Diffractometer	CCD area detector
Radiation source	fine-focus sealed tube, MoK α
Generator power	1600 watts (50 kV, 32mA)
Detector distance	5.8 cm
Data collection method	phi and omega scans
Theta range for data collection	1.93 to 28.42°
Index ranges	-12 ≤ <i>h</i> ≤ 12, -27 ≤ <i>k</i> ≤ 28, -28 ≤ <i>l</i> ≤ 25

Table C39. Atomic coordinates and equivalent isotropic atomic displacement parameters (Å²) for 4.7a.

U(eq) is defined as one third of the trace of the orthogonalized U_{ij} tensor.

Table C45. Crystal data and structure refinement for 4.8a.

Identification code	yzl3s
Empirical formula	C ₄₂ H ₆₂ ClN ₄ O ₄ P ₂
Formula weight	784.35
Temperature/K	293(2)
Crystal system	N/A
Space group	Pnma
a/Å	20.913(3)
b/Å	21.309(3)

$c/\text{\AA}$	9.4587(14)
$\alpha/^\circ$	90.00
$\beta/^\circ$	90.00
$\gamma/^\circ$	90.00
Volume/ \AA^3	4215.1(11)
Z	4
$\rho_{\text{calc}}/\text{g/cm}^3$	1.236
μ/mm^{-1}	0.211
F(000)	1684.0
Crystal size/ mm^3	$0.22 \times 0.14 \times 0.13$
Radiation	MoK α ($\lambda = 0.71073$)
2θ range for data collection/ $^\circ$	3.9 to 56.74
Index ranges	$-27 \leq h \leq 27, -28 \leq k \leq 27, -11 \leq l \leq 12$
Reflections collected	33490
Independent reflections	5364 [$R_{\text{int}} = 0.0944, R_{\text{sigma}} = \text{N/A}$]
Data/restraints/parameters	5364/0/261
Goodness-of-fit on F^2	1.332
Final R indexes [$I \geq 2\sigma(I)$]	$R_1 = 0.1691, wR_2 = 0.3562$
Final R indexes [all data]	$R_1 = 0.2023, wR_2 = 0.3906$
Largest diff. peak/hole / $e \text{\AA}^{-3}$	5.86/-0.68

Table C46. Fractional Atomic Coordinates ($\times 10^4$) and Equivalent Isotropic Displacement Parameters ($\text{\AA}^2 \times 10^3$) for 4.8a. U_{eq} is defined as 1/3 of the trace of the orthogonalised UIJ tensor.

Table C52. Atomic Occupancy for 4.8a.

<i>Atom Occupancy</i>	<i>Atom Occupancy</i>	<i>Atom Occupancy</i>
H33A 0.50	H33B 0.50	H33C 0.50
H42A 0.50	H42B 0.50	H42C 0.50

Experimental

Single crystals of C₄₂H₆₂ClN₄O₄P₂ [yzl3s] were []. A suitable crystal was selected and [] on a diffractometer. The crystal was kept at 293(2) K during data collection. Using Olex2 [1], the structure was solved with the ShelXS-1997 [2] structure solution program using Direct Methods and refined with the XL [3] refinement package using Least Squares minimisation.

Crystal structure determination of [yzl3s]

Crystal Data for C₄₂H₆₂ClN₄O₄P₂ (*M* = 784.35 g/mol): , space group Pnma (no. 62), *a* = 0.913(3) Å, *b* = 21.309(3) Å, *c* = 9.4587(14) Å, *V* = 4215.1(11) Å³, *Z* = 4, *T* = 293(2) K, $\mu(\text{MoK}\alpha) = 0.211 \text{ mm}^{-1}$, *D*_{calc} = 1.236 g/cm³, 33490 reflections measured (3.9° ≤ 2 Θ ≤ 56.74°), 5364 unique (*R*_{int} = 0.0944, *R*_{sigma} = N/A) which were used in all calculations. The final *R*₁ was 0.1691 (>2 σ (*I*)) and *wR*₂ was 0.3906 (all data).

Refinement model description

Number of restraints - 0, number of constraints - unknown.

This report has been created with Olex2, compiled on 2017.07.20 svn.r3457 for OlexSys. Please [let us know](#) if there are any errors or if you would like to have additional features.

Curriculum Vitae

for

Yi-Chun Lin

Education

PhD in chemistry September 2017
Massachusetts Institute of Technology
Cambridge, MA, USA

MSc in chemistry (July 2006)
National Tsing Hua University
Hsinchu, Taiwan ROC

BSc in chemistry (June 2003)
National Dong Hwa University
Hualien, Taiwan ROC

Experience

The Pennsylvania State University
Graduate Research and Teaching Assistant, 2011 – 2016.

Institute of Chemistry, Academia Sinica, Taiwan
Research Assistant, 2006 – 2011.
